"YOU CAN DO ANYTHING IF YOU SET YOUR MIND TO IT, I TEACH GEOMETRY TO JEE ASPIRANTS BUT BELIEVE THE MOST IMPORTANT FORMULA IS COURAGE + DREAMS = SUCCESS"

It is a matter of great pride and honour for me to have received such an overwhelming response to the previous editions of this book from the readers. In a way, this has inspired me to revise this book thoroughly as per the changed pattern of JEE Main & Advanced. I have tried to make the contents more relevant as per the needs of students, many topics have been re-written, a lot of new problems of new types have been added in etc. All possible efforts are made to remove all the printing errors that had crept in previous editions. The book is now in such a shape that the students would feel at ease while going through the problems, which will in turn clear their concepts too.

# A Summary of changes that have been made in Revised & Enlarged Edition

- Theory has been completely updated so as to accommodate all the changes made in JEE Syllabus & Pattern in recent years.
- The most important point about this new edition is, now the whole text matter of each chapter has been divided into small sessions with exercise in each session. In this way the reader will be able to go through the whole chapter in a systematic way.
- Just after completion of theory, Solved Examples of all JEE types have been given, providing the students a complete understanding of all the formats of JEE questions & the level of difficulty of questions generally asked in JEE.
- Along with exercises given with each session, a complete cumulative exercises have been given at the end of each chapter so as to give the students complete practice for JEE along with the assessment of knowledge that they have gained with the study of the chapter.
- Last 10 Years questions asked in JEE Main & Adv, IIT-JEE & AIEEE have been covered in all the chapters.

However I have made the best efforts and put my all teaching experience in revising this book. Still I am looking forward to get the valuable suggestions and criticism from my own fraternity i.e. the fraternity of JEE teachers.

I would also like to motivate the students to send their suggestions or the changes that they want to be incorporated in this book. All the suggestions given by you all will be kept in prime focus at the time of next revision of the book.

# **Session 1**

# Scalar and Vector Quantities, Representation of Vectors, Position Vector of a Point in Space, Direction Cosines, Rectangular Resolution of a Vector in 2D and 3D Systems

Vectors represent one of the most important mathematical systems, which is used to handle certain types of problems in Geometry, Mechanics and other branches of Applied Mathematics, Physics and Engineering.

# **Scalar and Vector Quantities**

Physical quantities are divided into two categories-Scalar quantities and Vector quantities. Those quantities which have only magnitude and which are not related to any fixed direction in space are called scalar quantities or briefly scalars. Examples of scalars are mass, volume, density, work, temperature etc.

A scalar quantity is represented by a real number along with a suitable unit. Second kind of quantities are those which have both magnitude and direction, such quantities are called vectors. Displacement, velocity, acceleration, momentum, weight, force etc., are examples of vector quantities.

# **Example 1.** Classify the following measures as scalars and vectors

- (i) 20 m north-west (ii) 10 Newton
- (iii) 30 km/h
- (iv) 50m/s towards north
- (v)  $10^{-19}$  coloumb

**Sol.** (i) Directed distance -Vector

- (ii) Force-Vector
- (iii) Speed-Scalar
- (iv) Velocity-Vector
- (v) Electric charge-Scalar

# **Representation of Vectors**

Geometrically, a vector is represented by a directed line segment.

For example,  $\mathbf{a} = \mathbf{A}\mathbf{B}$ . Here, A is called the initial point and B is called the terminal point or tip.

A directed line segment with initial point A and terminal point B is denoted by  $\overline{AB}$  or  $\overline{AB}$ . Vectors are also denoted by small letters with an arrow above it or by small bold

letters, e.g. **a, b, c** etc. or  $\overrightarrow{a}, \overrightarrow{b}, \overrightarrow{c}$  etc.

Here, in the figure  $\mathbf{a} = \mathbf{A}\mathbf{B}$  and magnitude or modulus of  $\mathbf{a}$  is expressed as  $|\mathbf{a}| = |\mathbf{A}\mathbf{B}| = AB$  (Distance between initial and terminal points).

### Remarks

- 1. The magnitude of a vector is always a non-negative real number
- 2. Every vector **AB** has the following three characteristics

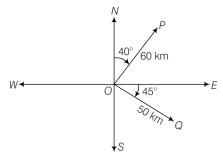

**Length** The length of AB will be denoted by |AB| or AB. **Support** The line of unlimited length of which AB is a segment is called the support of the vector AB.

**Sense** The sense of AB is from A to B and that of BA is from B to A. Thus, the sense of a directed line segment is from its initial point to the terminal point.

# **Example 2.** Represent graphically

- (i) A displacement of 60 km, 40° east of north
- (ii) A displacement of 50 km south-east

**Sol.**(i) The vector **OP** represent the required vector.

(ii) The vector **OO** represent the required vector.

# **Types of Vectors**

- 1. **Zero or null vector** A vector whose magnitude is zero is called zero or null vector and it is represented by 0. The initial and terminal points of the directed line segment representing zero vector are coincident and its direction is arbitrary.
- 2. **Unit vector** A vector whose modulus is unity, is called a unit vector. The unit vector in the direction of a vector  $\mathbf{a}$  is denoted by  $\hat{\mathbf{a}}$ , read as "a cap". Thus,  $|\hat{\mathbf{a}}| = 1.$

$$\hat{\mathbf{a}} = \frac{\mathbf{a}}{|\mathbf{a}|} = \frac{\text{Vector}}{\text{Magnitude of } a}$$

- 3. Like and unlike vectors Vectors are said to be like when they have the same sense of direction and unlike when they have opposite directions.
- 4. Collinear or parallel vectors Vectors having the same of parallel supports are called collinear vectors.
- 5. **Coinitial vectors** Vectors having the same initial point are called coinitial vectors.
- 6. **Coplanar vectors** A system of vectors is said to be coplanar, if they lie in the same plane or their supports are parallel to the same plane.
- 7. Coterminous vectors Vectors having the same terminal points are called coterminous vectors.
- 8. **Negative of a vector** The vector which has the same magnitude as the given vector **a** but opposite direction, is called the negative of a and is denoted by -a. Thus, if PQ = a, then QP = -a.
- 9. **Reciprocal of a vector** A vector having the same direction as that of a given vector *a* but magnitude equal to the reciprocal of the given vector is known as the reciprocal of a and is denoted by  $\mathbf{a}^{-1}$ . Thus, if  $|{\bf a}| = a$ , then  $|{\bf a}^{-1}| = 1/a$ .

### Remark

A unit vector is self reciprocal.

- 10. **Localised vector** A vector which is drawn parallel to a given vector through a specified point in space is called a localised vector. For example, a force acting on a rigid body is a localised vector as its effect depends on the line of action of the force.
- 11. Free vectors If the value of a vector depends only on its length and direction and is independent of its position in the space, it is called a free vector.

### Remark

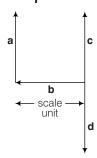

Unless otherwise stated all vectors will be considered as free vectors.

- 12. **Equality of vectors** Two vectors **a** and **b** are said to be equal, if
  - (i) |a| = |b|
  - (ii) they have the same or parallel support.
  - (iii) they have the same sense.

Two unit vectors may not be equal unless they have the same direction.

# **Example 3.** In the following figure, which of the vectors are:

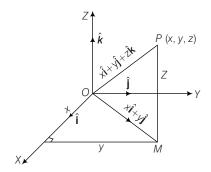

- (i) Collinear
- (ii) Equal
- (iii) Co-initial
- (iv) Collinear but not equal

- **Sol.** (i) a,c and d are collinear vectors.
  - (ii) a and c are equal vectors
  - (iii) b,c and d are co-initial vectors
  - (iv) a and d are collinear but they are not equal, as their directions are not same.

# **Position Vector of** a Point in Space

Let O be the fixed point in space and X'OX, Y'OY and Z'OZ be three lines perpendicular to each other at O. Then, these three lines called *X*-axis, *Y*-axis and *Z*-axis which constitute the rectangular coordinate system. The planes XOY, YOZ and ZOX, called respectively, the XY-plane, the YZ-plane and the ZX-plane.

Now, let P be any point in space. Then, position of P is given by triad (x, y, z) where x, y, z are perpendicular distance from YZ-plane, ZX-plane and XY-plane respectively.

The vector **OP** is called the position vector of point *P* with respect to the origin *O* and written as

$$\mathbf{OP} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$$

where  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  are unit vectors parallel to *X*-axis, *Y*-axis and *Z*-axis. We usually denote position vector by  $\mathbf{r}$ .

### Remarks

- **1.** If A and B are any two points in space having coordinates  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  respectively, then distance between the points A and  $B = \sqrt{(x_2 x_1)^2 + (y_2 y_1)^2 + (z_2 z_1)^2}$ .
- **2.** Using distance formula, the magnitude of **OP** (or **r**) is given by  $|\mathbf{OP}| = \sqrt{(x-0)^2 + (y-0)^2 + (z-0)^2} = \sqrt{x^2 + y^2 + z^2}$
- **3.** Two vectors are equal if they have same components. i.e. if  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$  and  $\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$  are equal, then  $a_1 = b_1$ ,  $a_2 = b_2$  and  $a_3 = b_3$ .

# **Example 4.** Find a unit vector parallel to the vector $-3\hat{\mathbf{i}} + 4\hat{\mathbf{j}}$ .

**Sol.** Let 
$$\mathbf{a} = -3\hat{\mathbf{i}} + 4\hat{\mathbf{j}}$$

Then, 
$$|\mathbf{a}| = \sqrt{(-3)^2 + (4)^2} = 5$$

$$\therefore$$
 Unit vector parallel to  $\mathbf{a} = \hat{\mathbf{a}} = \frac{1}{|\mathbf{a}|} \cdot \mathbf{a}$ 

$$= \frac{-3\hat{\mathbf{i}} + 4\hat{\mathbf{j}}}{5} = \frac{-3}{5}\hat{\mathbf{i}} + \frac{4}{5}\hat{\mathbf{j}}$$

# **Example 5.** Let $\mathbf{a} = 12\hat{\mathbf{i}} + n\hat{\mathbf{j}}$ and $|\mathbf{a}| = 13$ , find the value of n.

**Sol.** Here,  $\mathbf{a} = 12\hat{\mathbf{i}} + n\hat{\mathbf{j}}$ 

$$\Rightarrow |\mathbf{a}| = \sqrt{12^2 + n^2} = 13$$

$$\Rightarrow 144 + n^2 = 169$$

$$\Rightarrow \qquad n^2 = 25 \text{ or } n = \pm 5$$

# **Example 6.** Write two vectors having same magnitude.

Sol. Let 
$$\mathbf{a} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$$
 and  $\mathbf{b} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ 

Then, 
$$|\mathbf{a}| = |\mathbf{b}| = \sqrt{2^2 + 1^2 + 1^2} = \sqrt{6}$$

# **Example 7.** If one side of a square be represented by the vectors $3\hat{i} + 4\hat{j} + 5\hat{k}$ , then the area of the square is

# **Sol.** (d) Let $\mathbf{a} = 3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$ then $|\mathbf{a}|$

$$=\sqrt{3^2+4^2+5^2}=\sqrt{9+16+25}=5\sqrt{2}$$

Thus, the length of a side of square =  $5\sqrt{2}$ 

Hence, area of square =  $(5\sqrt{2})^2 = 25 \times 2 = 50$ 

# **Direction Cosines**

Let  $\mathbf{r}$  be the position vector of a point P(x, y, z). Then, direction cosines of  $\mathbf{r}$  are the cosines of angles  $\alpha$ ,  $\beta$  and  $\gamma$  that the vector  $\mathbf{r}$  makes with the positive direction of X, Y and Z-axes respectively. We usually denote direction cosines by l, m and n respectively.

In the figure, we may note that  $\Delta OAP$  is right angled triangle and in it we have

$$\cos \alpha = \frac{x}{r} (r \text{ stands for } | \mathbf{r} |)$$

Similarly, from the right angled triangles *OBP* and *OCP*, we get

$$\cos \beta = \frac{y}{r}$$
 and  $\cos \gamma = \frac{z}{r}$ 

Thus, we have the following

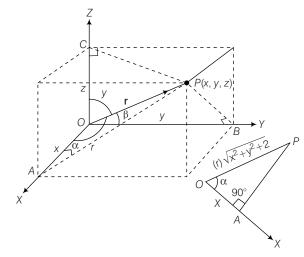

$$\cos \alpha = l = \frac{x}{\sqrt{x^2 + y^2 + z^2}} = \frac{x}{|\mathbf{r}|} = \frac{x}{r}$$

$$\cos \beta = m = \frac{y}{\sqrt{x^2 + y^2 + z^2}} = \frac{y}{|\mathbf{r}|} = \frac{y}{r}$$

and 
$$\cos \gamma = n = \frac{z}{\sqrt{x^2 + y^2 + z^2}} = \frac{z}{|\mathbf{r}|} = \frac{z}{r}$$

$$l^2 + m^2 + n^2 = 1.$$

Here,  $\alpha = \angle POX$ ,  $\beta = \angle POY$ ,  $\gamma = \angle POZ$  and  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  are the unit vectors along *OX*, *OY* and *OZ* respectively.

### Remarks

- **1.** The coordinates of point *P* may also be expressed as
- **2.** The numbers *Ir*, *mr* and *nr*, proportional to the direction cosines, are called the direction ratios of vector r and are denoted by a, b and c respectively.
- 3. If  $\mathbf{r} = a\hat{\mathbf{i}} + b\hat{\mathbf{j}} + c\hat{\mathbf{k}}$ , then a, b and c are direction ratios of the given vector.

Also, if  $a^2 + b^2 + c^2 = 1$ , then a, b and c will be direction cosines of given vector.

# Example 8. The direction cosines of the vector $3\hat{i} - 4\hat{i} + 5\hat{k}$ are

(a) 
$$\frac{3}{5}$$
,  $\frac{-4}{5}$ ,  $\frac{1}{5}$ 

(a) 
$$\frac{3}{5}$$
,  $\frac{-4}{5}$ ,  $\frac{1}{5}$  (b)  $\frac{3}{5\sqrt{2}}$ ,  $\frac{-4}{5\sqrt{2}}$ ,  $\frac{1}{\sqrt{2}}$ 

(c) 
$$\frac{3}{\sqrt{2}}$$
,  $\frac{-4}{\sqrt{2}}$ ,  $\frac{1}{\sqrt{2}}$ 

(c) 
$$\frac{3}{\sqrt{2}}$$
,  $\frac{-4}{\sqrt{2}}$ ,  $\frac{1}{\sqrt{2}}$  (d)  $\frac{3}{5\sqrt{2}}$ ,  $\frac{4}{5\sqrt{2}}$ ,  $\frac{1}{\sqrt{2}}$ 

**Sol.** (b) 
$$\mathbf{r} = 3\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$$

$$\Rightarrow$$
  $|\mathbf{r}| = \sqrt{3^2 + (-4)^2 + 5^2} = 5\sqrt{2}$ 

Hence, direction cosines are  $\frac{3}{5\sqrt{2}}$ ,  $\frac{-4}{5\sqrt{2}}$ ,  $\frac{5}{5\sqrt{2}}$ 

i.e. 
$$\frac{3}{5\sqrt{2}}, \frac{-4}{5\sqrt{2}}, \frac{1}{\sqrt{2}}$$

# **Example 9.** Show that the vector $\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$ is equally inclined to the axes OX, OY and OZ.

**Sol.** Let 
$$\mathbf{a} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$$

If **a** makes angles  $\alpha$ ,  $\beta$ ,  $\gamma$  with X, Y and Z-axes respectively,

$$\cos\alpha = \frac{1}{\sqrt{1^2 + 1^2 + 1^2}} = \frac{1}{\sqrt{3}}$$

$$\cos\beta = \frac{1}{\sqrt{3}}$$

and

$$\cos \gamma = \frac{1}{\sqrt{3}}$$

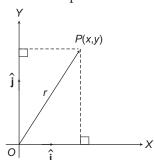

Thus, we have  $\cos \alpha = \cos \beta = \cos \gamma$ , i.e.  $\alpha = \beta = \gamma$ Hence, a is equally inclined to the axes.

# Rectangular Resolution of a **Vector in 2D and 3D Systems**

# In Two Dimensional System

Any vector  $\mathbf{r}$  in two dimensional system can be expressed as  $\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}}$ . The vectors  $x\hat{\mathbf{i}}$  and  $y\hat{\mathbf{j}}$  are called the perpendicular component vectors of **r**.

The scalars x and y are called the components or resolved parts of  $\mathbf{r}$  in the directions of X-axis and Y-axis, respectively and the ordered pair (x, y) is known as coordinates of point whose position vector is **r**.

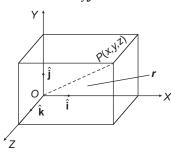

Also, the magnitude of  $\mathbf{r} = \sqrt{x^2 + y^2}$  and if  $\theta$  is the inclination of **r** with the *X*-axis, then  $\theta = \tan^{-1} \left( \frac{y}{r} \right)$ .

# In three Dimensional System

Any vector  $\mathbf{r}$  in three dimensional system can be expressed as

$$\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$$

The vectors  $x\hat{\mathbf{i}}$ ,  $y\hat{\mathbf{j}}$  and  $z\hat{\mathbf{k}}$  are called the right angled components of r.

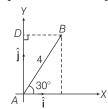

The scalars x, y and z are called the components or resolved parts of  $\mathbf{r}$  in the directions of X-axis, Y-axis and Z-axis, respectively and ordered triplet (x, y, z) is known as coordinates of P whose position vector is  $\mathbf{r}$ . Also, the magnitude or modulus of

$$\mathbf{r} = |\mathbf{r}| = \sqrt{x^2 + y^2 + z^2}$$
.

Example 10. Let AB be a vector in two dimensional plane with the magnitude 4 units and making an angle of 30° with X-axis and lying in the first quadrant.

Find the components of AB along the two axes of coordinates. Hence, represent AB in terms of unit vectors i and j.

**Sol.** Let us consider *A* as origin. From the diagram, it can be seen that the component of **AB** along *X*-axis

$$= AB \cos 30^{\circ} = 4 \cos 30^{\circ}$$
$$= 4 \times \frac{\sqrt{3}}{2} = 2\sqrt{3}$$

and the component of **AB** along Y-axis

$$= AB \sin 30^\circ = 4 \times \frac{1}{2} = 2$$

Hence, 
$$\mathbf{AB} = 2\sqrt{3}\hat{\mathbf{i}} + 2\hat{\mathbf{j}}$$

# **Session 2**

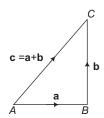

# Addition & Subtraction of Vectors, Multiplication of Vector by Scalar, Section Formula

# **Addition of Vectors**

(Resultant of Vectors)

# 1. Triangle Law of Addition

If two vectors are represented by two consecutive sides of a triangle, then their sum is represented by the third side of the triangle, but in opposite direction. This is known as the triangle law of addition of vectors. Thus, if AB = a, BC = b and AC = c, then AB + BC = AC i.e. a + b = c.

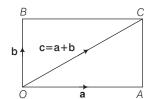

# 2. Parallelogram Law of Addition

If two vectors are represented by two adjacent sides of a parallelogram, then their sum is represented by the diagonal of the parallelogram whose initial point is the same as the initial point of the given vectors. This is known as parallelogram law of vector addition.

Thus, if OA = a, OB = b and OC = c

Then, OA + OB = OC i.e. a + b = c, where OC is a diagonal of the parallelogram OACB.

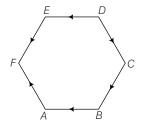

### Remarks

- The magnitude of a + b is not equal to the sum of the magnitudes of a and b.
- 2. From the figure, we have **OA** + **AC** = **OC** (By triangle law of vector addition)

or  $\mathbf{OA} + \mathbf{OB} = \mathbf{OC}$  (:  $\mathbf{AC} = \mathbf{OB}$ ), which is the parallelogram law. Thus, we may say that the two laws of vector addition are equivalent to each other.

# 3. Polygon law of addition

If the number of vectors are represented by the sides of a polygon taken in order, the resultant is represented by the closing side of the polygon taken in the reverse order.

In the figure, AB + BC + CD + DE + EF = AF

# 4. Addition in Component Form

If the vectors are defined in terms of  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$ , i.e. if  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$  and  $\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$ , then their sum is defined as

$$\mathbf{a} + \mathbf{b} = (a_1 + b_1) \,\hat{\mathbf{i}} + (a_2 + b_2) \,\hat{\mathbf{j}} + (a_3 + b_3) \,\hat{\mathbf{k}}.$$

# **Properties of Vector Addition**

Vector addition has the following properties

- (i) **Closure** The sum of two vectors is always a vector.
- (ii) **Commutativity** For any two vectors **a** and **b**,  $\Rightarrow$   $\mathbf{a} + \mathbf{b} = \mathbf{b} + \mathbf{a}$
- (iii)  $Associativity \ \mbox{For any three vectors } a,\,b \ \mbox{and } c,$

$$\Rightarrow$$
  $a + (b+c) = (a+b) + c$ 

(iv) **Identity** Zero vector is the identity for addition. For any vector  $\mathbf{a}$ .

$$\Rightarrow \qquad \qquad \mathbf{0} + \mathbf{a} = \mathbf{a} = \mathbf{a} + \mathbf{0}$$

(v) **Additive inverse** For every vector **a** its negative vector  $-\mathbf{a}$  exists such that  $\mathbf{a} + (-\mathbf{a}) = (-\mathbf{a}) + \mathbf{a} = \mathbf{0}$  i.e.  $(-\mathbf{a})$  is the additive inverse of the vector **a**.

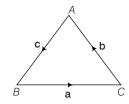

# **Example 11.** Find the unit vector parallel to the resultant vector of $2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$ and $\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$ .

**Sol.** Resultant vector,  $\mathbf{r} = (2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}}) + (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})$ =  $3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$  8

# **Example 12.** If a,b and c are the vectors represented by the sides of a triangle, taken in order, then prove that a + b + c = 0.

**Sol**. Let *ABC* be a triangle such that

$$BC = a$$
,  $CA = b$  and  $AB = c$ 

Then, 
$$\mathbf{a} + \mathbf{b} + \mathbf{c} = \mathbf{BC} + \mathbf{CA} + \mathbf{AB}$$
  

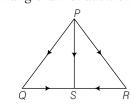

$$= \mathbf{BA} + \mathbf{AB}$$

$$= -\mathbf{AB} + \mathbf{AB}$$

$$\mathbf{a} + \mathbf{b} + \mathbf{c} = 0$$
Hence proved.

# **Example 13.** If S is the mid-point of side QR of a $\Delta PQR$ , then prove that PQ+PR=2PS.

Sol. Clearly, by triangle law of addition, we have

$$\mathbf{PQ} + \mathbf{QS} = \mathbf{PS} \qquad \dots (i)$$

On adding Eqs. (i) and (ii), we get

$$(PQ+QS)+(PR+RS)=2PS$$

PR + RS = PS

$$\Rightarrow$$
  $(PQ + PR) + (QS + RS) = 2PS$ 

$$\Rightarrow$$
 PQ + PR + 0 = 2PS

[: S is the mid-point of QR : QS = -RS]

Hence, PQ + PR = 2PS

Hence proved.

# **Example 14.** If ABCDEF is a regular hexagon, prove that AD+ EB+ FC = 4AB.

**Sol.** We have,

and

$$AD + EB + FC = (AB + BC + CD)$$
  
+  $(ED + DC + CB) + FC$   
=  $AB + (BC + CB) + (CD + DC) + ED + FC$ 

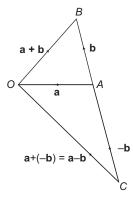

$$= AB + O + O + AB + 2AB = 4AB$$

$$(\because ED = AB, FC = 2AB)$$
Hence proved.

# **Subtraction of Vectors**

If **a** and **b** are two vectors, then their subtraction  $\mathbf{a} - \mathbf{b}$  is defined as  $\mathbf{a} - \mathbf{b} = \mathbf{a} + (-\mathbf{b})$ , where  $-\mathbf{b}$  is the negative of **b** having magnitude equal to that of **b** and direction opposite to **b**.

If 
$$\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$$
  
and  $\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$   
Then,  $\mathbf{a} - \mathbf{b} = (a_1 - b_1) \hat{\mathbf{i}} + (a_2 - b_2) \hat{\mathbf{j}} + (a_3 - b_3) \hat{\mathbf{k}}$ 

# **Properties of Vector Subtraction**

- (i)  $\mathbf{a} \mathbf{b} \neq \mathbf{b} \mathbf{a}$
- (ii)  $(a-b)-c \neq a-(b-c)$
- (iii) Since, any one side of a triangle is less than the sum and greater than the difference of the other two sides, so for any two vectors *a* and *b*, we have
  - (a)  $|a + b| \le |a| + |b|$
- (b)  $|a + b| \ge |a| |b|$
- (c)  $|a-b| \le |a| + |b|$
- $(d) |\mathbf{a} \mathbf{b}| \ge |\mathbf{a}| |\mathbf{b}|$

### Remark

If A and B are two points in space having coordinates  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$ , then

**AB** = Position Vector of *B* - Position Vector of *A*  
= 
$$(x_2\hat{\mathbf{i}} + y_2\hat{\mathbf{j}} + z_2\hat{\mathbf{k}}) - (x_1\hat{\mathbf{i}} + y_1\hat{\mathbf{j}} + z_1\hat{\mathbf{k}})$$
  
=  $(x_2 - x_1)\hat{\mathbf{i}} + (y_2 - y_1)\hat{\mathbf{j}} + (z_2 - z_1)\hat{\mathbf{k}}$ 

**Sol.** Here, 
$$AB = (1 - 0)\hat{i} + (0 - 1)\hat{j} = \hat{i} - \hat{j}$$
  
and  $CD = (2 - 1)\hat{i} + (1 - 2)\hat{j} = \hat{i} - \hat{j}$   
Clearly,  $AB = CD$  Hence proved.

**Example 16.** If the position vectors of A and B respectively  $\hat{\bf i} + 3\hat{\bf j} - 7\hat{\bf k}$  and  $5\hat{\bf i} - 2\hat{\bf j} + 4\hat{\bf k}$ , then find AB.

**Sol**. Let *O* be the origin, then we have

$$\mathbf{OA} = \hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 7\hat{\mathbf{k}}$$
and 
$$\mathbf{OB} = 5\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$
Now, 
$$\mathbf{AB} = \mathbf{OB} - \mathbf{OA} = (5\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) - (\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 7\hat{\mathbf{k}})$$

$$= 4\hat{\mathbf{i}} - 5\hat{\mathbf{j}} + 11\hat{\mathbf{k}}$$

**Example 17.** Vectors drawn from the origin ○ to the points A,B and C are respectively a,b and 4a – 3b. Find AC and BC.

Sol. We have, 
$$OA = a$$
,  $OB = b$  and  $OC = 4a - 3b$   
Clearly,  $AC = OC - OA = (4a - 3b) - (a)$   
 $= 3a - 3b$   
and  $BC = OC - OB = (4a - 3b) - (b) = 4a - 4b$ 

**Example 18.** Find the direction cosines of the vector joining the points A(1, 2, -3) and B(-1, -2, 1), directed from A to B.

Sol. Clearly,  

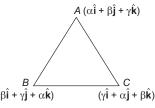

$$\mathbf{AB} = (-1 - 1)\hat{\mathbf{i}} + (-2 - 2)\hat{\mathbf{j}} + (1 + 3)\hat{\mathbf{k}} = -2\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$
Now,  $|\mathbf{AB}| = \sqrt{(-2)^2 + (-4)^2 + (4)^2} = \sqrt{36} = 6$   
∴ Unit vector along 
$$\mathbf{AB} = \frac{\mathbf{AB}}{|\mathbf{AB}|} = \frac{-2\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}}{6}$$

$$= -\frac{1}{3}\hat{\mathbf{i}} - \frac{2}{3}\hat{\mathbf{j}} + \frac{2}{3}\hat{\mathbf{k}}$$

- **Example 19.** Let  $\alpha, \beta$  and  $\gamma$  be distinct real numbers. The points with position vectors  $\alpha \hat{\mathbf{i}} + \beta \hat{\mathbf{j}} + \gamma \hat{\mathbf{k}}, \beta \hat{\mathbf{i}} + \gamma \hat{\mathbf{j}} + \alpha \hat{\mathbf{k}}$  and  $\gamma \hat{\mathbf{i}} + \alpha \hat{\mathbf{j}} + \beta \hat{\mathbf{k}}$ 
  - (a) are collinear
  - (b) form an equilateral triangle
  - (c) form a scalene triangle
  - (d) form a right angled triangle
- **Sol.** (b) Let the given points be A, B and C with position vectors  $\alpha \hat{\mathbf{i}} + \beta \hat{\mathbf{j}} + \gamma \hat{\mathbf{k}}$ ,  $\beta \hat{\mathbf{i}} + \gamma \hat{\mathbf{j}} + \alpha \hat{\mathbf{k}}$  and  $\gamma \hat{\mathbf{i}} + \alpha \hat{\mathbf{j}} + \beta \hat{\mathbf{k}}$ .

As,  $\alpha$ ,  $\beta$  and  $\gamma$  are distinct real numbers, therefore ABC form a triangle.

Clearly, 
$$\mathbf{A}\mathbf{B} = \mathbf{O}\mathbf{B} - \mathbf{O}\mathbf{A} = (\beta\hat{\mathbf{i}} + \gamma\hat{\mathbf{j}} + \alpha\hat{\mathbf{k}}) - (\alpha\hat{\mathbf{i}} + \beta\hat{\mathbf{j}} + \gamma\hat{\mathbf{k}})$$
  
=  $(\beta - \alpha)\hat{\mathbf{i}} + (\gamma - \beta)\hat{\mathbf{j}} + (\alpha - \gamma)\hat{\mathbf{k}}$ 

Now, 
$$|\mathbf{A}\mathbf{B}| = \sqrt{(\beta - \alpha)^2 + (\gamma - \beta)^2 + (\alpha - \gamma)^2}$$
  
Similarly,  $\mathbf{B}\mathbf{C} = \mathbf{C}\mathbf{A} = \sqrt{(\beta - \alpha)^2 + (\gamma - \beta)^2 + (\alpha - \gamma)^2}$ 

 $\therefore \Delta ABC$  is an equilateral triangle.

**Example 20.** If the position vectors of the vertices of a triangle be  $2\hat{i}+4\hat{j}-\hat{k}$ ,  $4\hat{i}+5\hat{j}+\hat{k}$  and  $3\hat{i}+6\hat{j}-3\hat{k}$ , then the triangle is

- (a) right angled
- (b) isosceles
- (c) equilateral
- (d) None of these

**Sol.** (a, b) Let A, B, C be the vertices of given triangle with position vectors,  $2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - \hat{\mathbf{k}}$ ,  $4\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 3\hat{\mathbf{k}}$  respectively.

Then, we have

$$\mathbf{OA} = 2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - \hat{\mathbf{k}}, \mathbf{OB} = 4\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + \hat{\mathbf{k}}$$
  
and 
$$\mathbf{OC} = 3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 3\hat{\mathbf{k}}$$
  
Clearly, 
$$\mathbf{AB} = \mathbf{OB} - \mathbf{OA} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

Clearly, 
$$\mathbf{AB} = \mathbf{OB} - \mathbf{OA} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$
$$\mathbf{BC} = -\hat{\mathbf{i}} + \hat{\mathbf{j}} - 4\hat{\mathbf{k}}$$

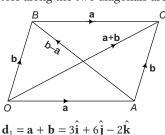

and 
$$\mathbf{AC} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$
  
Now,  $\mathbf{AB} = |\mathbf{AB}| = \sqrt{2^2 + 1^2 + 2^2} = 3$   
 $\mathbf{BC} = |\mathbf{BC}| = \sqrt{(-1)^2 + (1)^2 + (-4)^2} = 3\sqrt{2}$   
and  $\mathbf{AC} = |\mathbf{AC}| = \sqrt{1^2 + 2^2 + (-2)^2} = 3$   
 $\therefore AB = AC \text{ and } BC^2 = AB^2 + AC^2$ 

.. The triangle is isosceles and right angled.

**Example 21.** The two adjacent sides of a parallelogram are  $2\hat{i} + 4\hat{j} - 5\hat{k}$  and  $\hat{i} + 2\hat{j} + 3\hat{k}$ . Find the unit vectors along the diagonals of the parallelogram.

**Sol.** Let *OABC* be the given parallelogram and let the adjacent sides *OA* and *OB* be represented by  $a = 2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$  and  $b = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  respectively.

Now, the vectors along the two diagonals are

The required unit vectors are

$$\hat{\mathbf{n}}_{1} = \frac{\mathbf{d}_{1}}{|\mathbf{d}_{1}|} = \frac{3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}}}{\sqrt{3^{2} + 6^{2} + (-2)^{2}}}$$

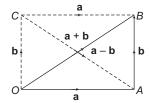

$$= \frac{3}{7}\hat{\mathbf{i}} + \frac{6}{7}\hat{\mathbf{j}} - \frac{2}{7}\hat{\mathbf{k}}$$

$$\hat{\mathbf{n}}_{2} = \frac{d_{2}}{|d_{2}|} = \frac{-\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 8\hat{\mathbf{k}}}{\sqrt{(-1)^{2} + (-2)^{2} + 8^{2}}}$$

$$= \frac{-1}{2\sqrt{69}}\hat{\mathbf{i}} - \frac{2}{2\sqrt{69}}\hat{\mathbf{j}} + \frac{8}{2\sqrt{69}}\hat{\mathbf{k}}$$

**Example 22.** If a and b are any two vectors, then give the geometrical interpretation of the relation  $|\mathbf{a}+\mathbf{b}| = |\mathbf{a}-\mathbf{b}|$ .

**Sol.** Let OA = a and AB = b. Completing the parallelogram OABC.

Then.

$$OC = b$$
 and  $CB = a$ 

From  $\triangle OAB$ , we have

$$OA + AB = OB \implies a + b = OB$$
 ...(i

From  $\triangle OCA$ , we have

$$OC + CA = OA$$

$$\Rightarrow b + CA = a \Rightarrow CA = a - b \qquad ...(ii)$$
Clearly,  $|a + b| = |a - b| \Rightarrow |OB| = |CA|$ 
Diagonals of parallelogram  $OABC$  are equal

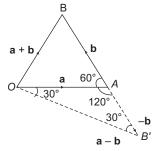

Diagonals of parallelogram OABC are equal.

OABC is a rectangle.

$$\Rightarrow$$
 OA  $\perp$  OC  $\Rightarrow$  a  $\perp$  b

**Example 23.** If the sum of two unit vectors is a unit vector, prove that the magnitude of their difference is  $\sqrt{3}$ .

**Sol.** Let  $\hat{\mathbf{a}}$  and  $\hat{\mathbf{b}}$  be two unit vectors represented by sides OA and AB of a  $\triangle OAB$ .

Then,  $\mathbf{OA} = \hat{\mathbf{a}}, \mathbf{AB} = \hat{\mathbf{b}}$ 

$$OB = OA + AB = \hat{a} + \hat{b}$$

(using triangle law of vector addition)

It is given that, 
$$|\hat{\mathbf{a}}| = |\hat{\mathbf{b}}| = |\hat{\mathbf{a}} + \hat{\mathbf{b}}| = 1$$
  
 $\Rightarrow |\mathbf{O}\mathbf{A}| + |\mathbf{A}\mathbf{B}| = |\mathbf{O}\mathbf{B}| = 1$   
 $\triangle OAB$  is equilateral triangle.  
Since,  $|\mathbf{O}\mathbf{A}| = |\hat{\mathbf{a}}| = 1 = |-\hat{\mathbf{b}}| = |\mathbf{A}\mathbf{B}'|$   
Therefore,  $\triangle OAB'$  is an isosceles triangle.  
 $\Rightarrow \angle AB'O = \angle AOB' = 30^{\circ}$   
 $\Rightarrow \angle BOB' = \angle BOA + \angle AOB' = 60^{\circ} + 30^{\circ} = 90^{\circ}$   
(since,  $\triangle BOB'$  is right angled)  
 $\therefore$  In  $\triangle BOB'$ , we have  
 $|BB'|^2 = |OB|^2 + |OB'|^2$   
 $= |\hat{\mathbf{a}} + \hat{\mathbf{b}}|^2 + |\hat{\mathbf{a}} - \hat{\mathbf{b}}|^2$   
 $2^2 = 1^2 + |\hat{\mathbf{a}} - \hat{\mathbf{b}}|^2$ 

Hence proved.

# Multiplication of a Vector by a Scalar

 $|\hat{\mathbf{a}} - \hat{\mathbf{b}}| = \sqrt{3}$ 

If  $\mathbf{a}$  is a vector and m is a scalar (i.e. a real number), then  $m \mathbf{a}$  is a vector whose magnitude is m times that of  $\mathbf{a}$  and whose direction is the same as that of  $\mathbf{a}$ , if m is positive and opposite to that of a, if m is negative.

 $\therefore$  Magnitude of  $ma = |m\mathbf{a}| \Rightarrow m$  (magnitude of  $\mathbf{a}$ ) =  $m |\mathbf{a}|$ Again, if  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$ , then  $m \mathbf{a} = (ma_1) \hat{\mathbf{i}} + (ma_2) \hat{\mathbf{j}} + (ma_3) \hat{\mathbf{k}}$ 

# **Properties of Multiplication** of Vectors by a Scalar

The following are properties of multiplication of vectors by scalars, for vectors **a**, **b** and scalars *m*, *n* 

(i) 
$$m(-a) = (-m) a = -(ma)$$

- (ii) (-m)(-a) = m a
- (iii)  $m(n\mathbf{a}) = (mn) \mathbf{a} = n(m\mathbf{a})$
- (iv) (m+n)  $\mathbf{a} = m\mathbf{a} + n\mathbf{a}$
- (v) m(a + b) = m a + m b

**Example 24.** If a is a non-zero vector of modulus a and m, is a non-zero scalar, then ma is a unit vector, if

(a) 
$$m = \pm 1$$

(b) 
$$m = |a|$$

(c) 
$$m = \frac{1}{|\mathbf{a}|}$$

(d) 
$$m = \pm 2$$

**Sol.** (c) Since,  $m\mathbf{a}$  is a unit vector,  $|m\mathbf{a}| = 1$ 

$$\Rightarrow |m| |\mathbf{a}| = 1$$

$$\Rightarrow |m| = \frac{1}{|\mathbf{a}|} \Rightarrow m = \pm \frac{1}{|\mathbf{a}|}$$

# **Example 25.** For a non-zero vector a, the set of real numbers, satisfying |(5-x)a| < |2a| consists of all x such that

(a) 
$$0 < x < 3$$

(b) 
$$3 < x < 7$$

(c) 
$$-7 < x < -3$$

(d) 
$$-7 < x < 3$$

**Sol.** (b) We have,  $|(5 - x) \mathbf{a}| < |2\mathbf{a}|$ 

$$|5 - x| |\mathbf{a}| < 2|\mathbf{a}|$$

$$\Rightarrow |5 - x| < 2$$

$$\Rightarrow -2 < 5 - x < 2$$

$$\Rightarrow 3 < x < 7$$

# **Example 26.** Find a vector of magnitude (5/2) units which is parallel to the vector 3i + 4j.

**Sol.** Here, 
$$\mathbf{a} = 3\hat{\mathbf{i}} + 4\hat{\mathbf{j}}$$

Then, 
$$|\mathbf{a}| = \sqrt{3^2 + 4^2} = 5$$

∴ A unit vector parallel to

$$\mathbf{a} = \hat{\mathbf{a}} = \frac{a}{|\mathbf{a}|} \cdot = \frac{1}{5} (3\hat{\mathbf{i}} + 4\hat{\mathbf{j}})$$
 ...(i)

Hence, the required vector of magnitude (5/2) units and parallel to a

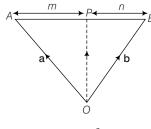

$$= \frac{5}{2} \cdot \hat{\mathbf{a}} = \frac{5}{2} \cdot \frac{1}{5} (3\hat{\mathbf{i}} + 4\hat{\mathbf{j}})$$
$$= \frac{1}{2} (3\hat{\mathbf{i}} + 4\hat{\mathbf{j}})$$

$$\mathbf{AD} = \frac{1}{4} (\hat{\mathbf{i}} + 5\hat{\mathbf{j}} - 12\hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}} - 3\hat{\mathbf{k}}) = \frac{1}{4} (-3\hat{\mathbf{i}} + 9\hat{\mathbf{j}})$$

$$= \frac{3}{4} (-\hat{\mathbf{i}} + 3\hat{\mathbf{j}})$$

$$|\mathbf{AD}| = \frac{3}{4} \sqrt{(-1)^2 + 3^2} = \frac{3}{4} \sqrt{10}$$

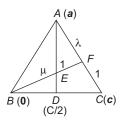

# **Example 30.** The median AD of the $\triangle$ ABC is bisected at E.BE meets AC in F. Then, AF: AC is equal to

- (a) 3/4

**Sol.** (b) Let position vector of *A* w.r.t. *B* is **a** and that of *C* w.r.t. *B* 

Position vector of D w.r.t.

$$B = \frac{0 + \mathbf{c}}{2} = \frac{\mathbf{c}}{2}$$

Position vector of

$$E = \frac{\mathbf{a} + \frac{\mathbf{c}}{2}}{2} = \frac{\mathbf{a}}{2} + \frac{\mathbf{c}}{4} \qquad \dots (i)$$

Let  $AF : FC = \lambda : 1$  and  $BE : EF = \mu : 1$

From Eqs. (i) and (ii), we get

From Eqs. (1) and (11), we get
$$\frac{\mathbf{a}}{2} + \frac{\mathbf{c}}{4} = \frac{\mu}{(1+\lambda)(1+\mu)} \mathbf{a} + \frac{\lambda \mu}{(1+\lambda)(1+\mu)} \mathbf{c}$$

$$\Rightarrow \qquad \frac{1}{2} = \frac{\mu}{(1+\lambda)(1+\mu)}$$
and
$$\frac{1}{4} = \frac{\lambda \mu}{(1+\lambda)(1+\mu)}$$

$$\Rightarrow \qquad \lambda = \frac{1}{2}$$

$$\therefore \frac{AF}{AC} = \frac{AF}{AF + FC} = \frac{\lambda}{1 + \lambda} = \frac{\frac{1}{2}}{\frac{3}{2}} = \frac{1}{3}$$

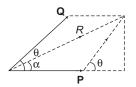

# Magnitude of Resultant of Two Vectors

Let **R** be the resultant of two vectors **P** and **Q**. Then,

$$\mathbf{R} = \mathbf{P} + \mathbf{Q}$$

$$|\mathbf{R}| = R = \sqrt{P^2 + Q^2 + 2PQ\cos\theta}$$

where,  $|\mathbf{P}| = P, |\mathbf{Q}| = Q$ ,  $\tan \alpha = \frac{Q \sin \theta}{P + Q \cos \theta}$ 

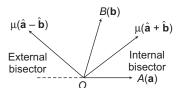

**Deduction** When  $|\mathbf{P}| = |\mathbf{Q}|$ , i.e. P = Q

$$\tan \alpha = \frac{P \sin \theta}{P + P \cos \theta}$$
$$= \frac{\sin \theta}{1 + \cos \theta} = \tan \frac{\theta}{2}$$
$$\alpha = \frac{\theta}{2}$$

Hence, the angular bisector of two unit vectors  $\boldsymbol{a}$  and  $\boldsymbol{b}$  is along the vector sum  $\mathbf{a} + \mathbf{b}$ .

# Remarks

- 1. The internal bisector of the angle between any two vectors is along the vector sum of the corresponding unit vectors.
- 2. The external bisector of the angle between two vectors is along the vector difference of the corresponding unit vectors.

# **Example 31.** The sum of two forces is 18 N and resultant whose direction is at right angles to the smaller force is 12 N. The magnitude of the two forces are

- (a) 13, 5
- (b) 12, 6
- (c) 14, 4

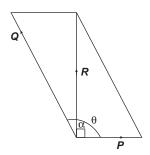

**Sol.** (a) We have, 
$$|\mathbf{P}| + |\mathbf{Q}| = 18N; |\mathbf{R}| = |\mathbf{P} + \mathbf{Q}| + 12 N$$

$$\alpha = 90^{\circ}$$

$$P + Q\cos\theta = 0$$

$$\Rightarrow Q\cos\theta = -P$$
Now.  $R^2 = P^2 + Q^2 + 2PQ\cos\theta$ 

$$\Rightarrow R^2 = P^2 + Q^2 + 2P(-P) = Q^2 - P^2$$

$$\Rightarrow 12^2 = (P+Q)(Q-P) = 18(Q-P)$$

$$\Rightarrow Q-P=8 \text{ and } Q+P=18$$

$$\Rightarrow Q=13, P=5$$

:. Magnitude of two forces are 5 N and 13 N.

**Example 32.** The length of longer diagonal of the parallelogram constructed on 5a+2b and a-3b, when it is given that  $|\mathbf{a}| = 2\sqrt{2}$ ,  $|\mathbf{b}| = 3$  and angle between a and b is  $\frac{\dot{\pi}}{\mu}$ , is

(b) 
$$\sqrt{113}$$

(c) 
$$\sqrt{593}$$

(d) 
$$\sqrt{369}$$

**Sol.** (c) Length of the two diagonals will be

$$d_1 = |(5\mathbf{a} + 2\mathbf{b}) + (\mathbf{a} - 3\mathbf{b})|$$

and 
$$d_2 = |(5\mathbf{a} + 2\mathbf{b}) - (\mathbf{a} - 3\mathbf{b})|$$
  
 $\Rightarrow d_1 = |6\mathbf{a} - \mathbf{b}|, d_2 = |4\mathbf{a} + 5\mathbf{b}|$ 

Thus,

$$d_1 = \sqrt{|6\mathbf{a}|^2 + |-\mathbf{b}|^2 + 2|6\mathbf{a}| |-\mathbf{b}|\cos(\pi - \pi/4)}$$
$$= \sqrt{36(2\sqrt{2})^2 + 9 + 12 \cdot 2\sqrt{2} \cdot 3 \cdot \left(-\frac{1}{\sqrt{2}}\right)} = 15$$

$$d_{2} = \sqrt{|4\mathbf{a}|^{2} + |5\mathbf{b}|^{2} + 2|4\mathbf{a}||5\mathbf{b}|\cos\frac{\pi}{4}}$$

$$= \sqrt{16 \times 8 + 25 \times 9 + 40 \times 2\sqrt{2} \times 3 \times \frac{1}{\sqrt{2}}}$$

$$= \sqrt{593}$$

 $\therefore$  Length of the longer diagonal =  $\sqrt{593}$ 

**Example 33.** The vector c, directed along the internal bisector of the angle between the vectors  $a = 7\hat{i} - 4\hat{j} - 4\hat{k}$  and  $b = -2\hat{i} - \hat{j} + 2\hat{k}$  with  $|c| = 5\sqrt{6}$ , is

(a) 
$$\frac{5}{3}(\hat{\bf i} - 7\hat{\bf j} + 2\hat{\bf k})$$

(b) 
$$\frac{5}{3}(5\hat{i}+5\hat{j}+2\hat{k})$$

 (b)  $\frac{5}{3}(5\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$  (c)  $\frac{5}{3}(\hat{\mathbf{i}} + 7\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$  (d)  $\frac{5}{3}(-5\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$ 

**Sol.** (a) Let  $\mathbf{a} = 7\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 4\hat{\mathbf{k}}$ 

and 
$$\mathbf{b} = -2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

Now, required vector  $\mathbf{c} = \lambda \left( \frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{b}}{|\mathbf{b}|} \right)$  $= \lambda \left( \frac{7\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 4\hat{\mathbf{k}}}{9} + \frac{-2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}}{3} \right)$ 

$$= \frac{\lambda}{9}(\hat{\mathbf{i}} - 7\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

$$|\mathbf{c}|^2 = \frac{\lambda^2}{81} \times 54 = 150$$

$$\Rightarrow$$
  $\lambda = \pm 15$ 

$$\Rightarrow \qquad \mathbf{c} = \pm \frac{5}{3} (\hat{\mathbf{i}} - 7\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

# **Session 3**

# Linear Combination of Vectors, Theorem on Coplanar & Non-coplanar Vectors, Linear Independence and Dependence of Vectors

# **Linear Combination of Vectors**

A vector **r** is said to be a linear combination of vectors **a**, **b** and **c**... etc., if there exist scalars x, y and z etc., such that  $\mathbf{r} = x\mathbf{a} + y\mathbf{b} + z\mathbf{c} + ...$ 

For examples Vectors  $\mathbf{r}_1 = 2\mathbf{a} + \mathbf{b} + 3\mathbf{c}$  and  $\mathbf{r}_2 = \mathbf{a} + 3\mathbf{b} + \sqrt{2}\mathbf{c}$  are linear combinations of the vectors  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$ .

# Collinearity and Coplanarity of Vectors

# Relation between Two Collinear Vectors (or Parallel Vectors)

Let **a** and **b** be two collinear vectors and let  $\hat{\mathbf{x}}$  be the unit vector in the direction of **a**. Then, the unit vector in the direction of **b** is  $\hat{\mathbf{x}}$  or  $-\hat{\mathbf{x}}$  according as **a** and **b** are like or unlike parallel vectors. Now,  $\mathbf{a} = |\mathbf{a}| \hat{\mathbf{x}}$  and  $\mathbf{b} = \pm |\mathbf{b}| \hat{\mathbf{x}}$ .

$$\therefore \mathbf{a} = \left(\frac{|\mathbf{a}|}{|\mathbf{b}|}\right) |\mathbf{b}| \hat{\mathbf{x}} \Rightarrow \mathbf{a} = \pm \left(\frac{|\mathbf{a}|}{|\mathbf{b}|}\right) \mathbf{b}$$

$$\Rightarrow$$
  $\mathbf{a} = \lambda \mathbf{b}$ , where  $\lambda = \pm \frac{|\mathbf{a}|}{|\mathbf{b}|}$ 

Thus, if **a** and **b** are collinear vectors, then  $\mathbf{a} = \lambda \mathbf{b}$  or  $\mathbf{b} = \lambda \mathbf{a}$  for some scalar  $\lambda$  i.e, there exist two non-zero scalar quantities x and y so that  $x\mathbf{a} + y\mathbf{b} = \mathbf{O}$ 

# An Important Theorem

**Theorem :** Vectors  $\mathbf{a}$  and  $\mathbf{b}$  are two non-zero, non-collinear vectors and x, y are two scalars such that

$$x\mathbf{a} + y\mathbf{b} = 0$$

Then.

$$x = 0, y = 0$$

**Proof** It is given that  $x\mathbf{a} + y\mathbf{b} = 0$ 

$$c\mathbf{a} + y\mathbf{b} = 0 \qquad \dots (i)$$

Suppose that  $x \neq 0$ , then dividing both sides of (i) by the scalar x, we get

$$\mathbf{a} = -\frac{y}{x}\mathbf{b} \qquad \dots (ii)$$

Now,  $\frac{y}{x}$  is a scalar, because x and y are scalars.

Hence, Eq. (ii) expresses  $\mathbf{a}$  as product of  $\mathbf{b}$  by a scalar, so that  $\mathbf{a}$  and  $\mathbf{b}$  are collinear. Thus, we arrive at a contradiction because  $\mathbf{a}$  and  $\mathbf{b}$  are given to be non-collinear.

Thus our supposition that  $x \neq 0$ , is wrong. Hence, x = 0. Similarly, y = 0

# Remarks

1. 
$$x\mathbf{a} + y\mathbf{b} = 0 \implies \begin{cases} \mathbf{a} = 0, \mathbf{b} = 0 \\ x = 0, y = 0 \end{cases}$$
or
$$\mathbf{a} \mid \mathbf{b}$$

**2.** If **a** and **b** are two non-collinear (or non-parallel) vectors, then  $x_1$ **a** +  $y_1$ **b** =  $x_2$ **a** +  $y_2$ **b** 

$$\Rightarrow \qquad x_1 = x_2 \quad \text{and} \quad y_1 = y_2$$

**Proof**  $x_1$ **a** +  $y_1$ **b** =  $x_2$ **b** +  $y_2$ **b** 

$$\Rightarrow (x_1 - x_2)\mathbf{a} + (y_1 - y_2)\mathbf{b} = 0$$

$$x_1 - x_2 = 0$$
 and  $y_1 - y_2 = 0$ 

[: 
$$\mathbf{a}$$
 and  $\mathbf{b}$  are non-collinear]

 $\Rightarrow x_1 = x_2 \text{ and } y_1 = y_2$ If  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$  and  $b = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$ , then  $\mathbf{a} \parallel \mathbf{b}$ 

$$\Rightarrow \frac{a_1}{b_1} = \frac{a_2}{b_2} = \frac{a_3}{b_3}$$

# Test of Collinearity of Three Points

- (i) Three points *A*, *B* and *C* are collinear, if  $AB = \lambda BC$
- (ii) Three points with position vectors **a**, **b** and **c** are collinear iff there exist scalars x, y and z not all zero such that  $x\mathbf{a} + y\mathbf{b} + z\mathbf{c} = 0$ , where x + y + z = 0

**Proof** Let us suppose that points A, B and C are collinear and their position vectors are  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  respectively. Let C divide the join of  $\mathbf{a}$  and  $\mathbf{b}$  in the ratio y:x. Then,

$$\mathbf{c} = \frac{x\mathbf{a} + y\mathbf{b}}{x + y}$$

or 
$$x\mathbf{a} + y\mathbf{b} - (x + y)\mathbf{c} = 0$$
  
or  $x\mathbf{a} + y\mathbf{b} + z\mathbf{c} = 0$ , where  $z = -(x + y)$ 

Also, 
$$x + y + z = x + y - (x + y) = 0$$

Conversely, let  $x\mathbf{a} + y\mathbf{b} + z\mathbf{c} = 0$ , where x + y + z = 0. Therefore,

or 
$$x\mathbf{a} + y\mathbf{b} = -z\mathbf{c} = (x + y)\mathbf{c} \quad (\because x + y = -z)$$
$$\mathbf{c} = \frac{x\mathbf{a} + y\mathbf{b}}{x + y}$$

This relation shows that **c** divides the join of **a** and **b** in the ratio y: x. Hence, the three points A, B and C are collinear.

(iii) If  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}}$ ,  $\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}}$  and  $\mathbf{c} = c_1 \hat{\mathbf{i}} + c_2 \hat{\mathbf{j}}$ , then the points with position vector **a**, **b** and **c** will be

collinear iff 
$$\begin{vmatrix} a_1 & a_2 & 1 \\ b_1 & b_2 & 1 \\ c_1 & c_2 & 1 \end{vmatrix} = 0.$$

**Proof** The points with position vector **a**, **b** and **c** will be collinear iff there exist scalars x, y and z not all zero such that,

$$x(a_1\hat{\mathbf{i}} + a_2\hat{\mathbf{j}}) + y(b_1\hat{\mathbf{i}} + b_2\hat{\mathbf{j}}) + z(c_1\hat{\mathbf{i}} + c_2\hat{\mathbf{j}}) = 0$$
 and  $x + y + z = 0$ 

$$\Rightarrow xa_1 + yb_1 + zc_1 = 0$$

$$xa_2 + yb_2 + zc_2 = 0$$

$$x + y + z = 0$$

Thus, the points will be collinear iff the above system of equation's have non-trivial solution

Hence, the points will be collinear

iff 
$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ 1 & 1 & 1 \end{vmatrix} = 0$$
 or  $\begin{vmatrix} a_1 & a_2 & 1 \\ b_1 & b_2 & 1 \\ c_1 & c_2 & 1 \end{vmatrix} = 0$ .

**Example 34.** Show that the vectors  $2\hat{i} - 3\hat{j} + 4\hat{k}$  and  $-4\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 8\hat{\mathbf{k}}$  are collinear.

**Sol.** Let 
$$\mathbf{a} = 2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$
 and  $\mathbf{b} = -4\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 8\hat{\mathbf{k}}$   
Consider,  $\mathbf{b} = -4\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 8\hat{\mathbf{k}} = -2(2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) = -2\mathbf{a}$ 

∴ The vectors **a** and **b** are collinear.

**Example 35. Show that the points** A(1, 2, 3), B(3, 4, 7)and C(-3, -2, -5) are collinear. Find the ratio in which point C divides AB.

Sol. Clearly, 
$$\mathbf{AB} = (3-1)\hat{\mathbf{i}} + (4-2)\hat{\mathbf{j}} + (7-3)\hat{\mathbf{k}}$$
  
 $= 2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$   
and  $\mathbf{BC} = (-3-3)\hat{\mathbf{i}} + (-2-4)\hat{\mathbf{j}} + (-5-7)\hat{\mathbf{k}}$   
 $= 6\hat{\mathbf{i}} - 6\hat{\mathbf{j}} - 12\hat{\mathbf{k}}$   
 $= -3(2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) = -3\mathbf{AB}$   
 $\Rightarrow \mathbf{BC} = -3\mathbf{AB}$ 

 $\therefore$  A, B and C are collinear.

Now, let C divide AB in the ratio k:1, then

$$\mathbf{OC} = \frac{k\mathbf{OB} + 1 \cdot \mathbf{OA}}{k+1}$$

$$\Rightarrow -3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 5\hat{\mathbf{k}} = \frac{k(3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 7\hat{\mathbf{k}}) + (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})}{k+1}$$

$$\Rightarrow -3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 5\hat{\mathbf{k}} = \left(\frac{3k+1}{k+1}\right)\hat{\mathbf{i}} + \left(\frac{4k+2}{k+1}\right)\hat{\mathbf{j}} + \left(\frac{7k+3}{k+1}\right)\hat{\mathbf{k}}$$

$$\Rightarrow \frac{3k+1}{k+1} = -3; \frac{4k+2}{k+1} = -2 \text{ and } \frac{7k+3}{k+1} = -5$$

From, all relations, we get  $k = \frac{-2}{3}$ 

Hence, C divides AB externally in the ratio 2:3.

**Example 36.** If the position vectors of A,B,C and D are  $2\hat{i} + \hat{j}$ ,  $\hat{i} - 3\hat{j}$ ,  $3\hat{i} + 2\hat{j}$  and  $\hat{i} + \lambda\hat{j}$ , respectively and AB || CD, then  $\lambda$  will be

(a) 
$$-8$$
 (b)  $-6$  (c)  $8$  (d)  $6$ 

Sol. (b) 
$$\mathbf{AB} = (\hat{\mathbf{i}} - 3\hat{\mathbf{j}}) - (2\hat{\mathbf{i}} + \hat{\mathbf{j}}) = -\hat{\mathbf{i}} - 4\hat{\mathbf{j}};$$
  
 $\mathbf{CD} = (\hat{\mathbf{i}} + \lambda\hat{\mathbf{j}}) - (3\hat{\mathbf{i}} + 2\hat{\mathbf{j}}) = -2\hat{\mathbf{i}} + (\lambda - 2)\hat{\mathbf{j}};$ 

$$\mathbf{CD} = (\mathbf{i} + \lambda \mathbf{j}) - (3\mathbf{i} + 2\mathbf{j}) = -2\mathbf{i} + (\lambda + 2\mathbf{j})$$

$$\mathbf{AB} \parallel \mathbf{CD} \Rightarrow \mathbf{AB} = x \mathbf{CD}$$

$$-\hat{\mathbf{i}} - 4\hat{\mathbf{j}} = x \{-2\hat{\mathbf{i}} + (\lambda - 2)\hat{\mathbf{j}}\}$$

$$\Rightarrow -1 = -2x, -4 = (\lambda - 2)x$$

$$\Rightarrow x = \frac{1}{2} \text{ and } \lambda = -6$$

Example 37. The points with position vectors  $60\mathbf{i} + 3\mathbf{j}$ ,  $40\mathbf{i} - 8\mathbf{j}$  and  $a\mathbf{i} - 52\mathbf{j}$  are collinear, if a is equal to

(a) 
$$-40$$

(d) None of these

Sol (a) The three points are collinear if

$$\begin{vmatrix} 60 & 3 & 1 \\ 40 & -8 & 1 \\ a & -52 & 1 \end{vmatrix} = 0$$

\Rightarrow 2640-120+3a-2080+8a=0

$$11a = -440$$

a = -40

- **Example 38.** Let a, b and c be three non-zero vectors such that no two of these are collinear. If the vector a+2b is collinear with c and b+3c is collinear with a ( $\lambda$  being some non-zero scalar), then a+2b+6c is equal to

**Sol.** (a) As  $\mathbf{a} + 2\mathbf{b}$  and  $\mathbf{c}$  are collinear  $\mathbf{a} + 2\mathbf{b} = \lambda \mathbf{c}$ 

Again,  $\mathbf{b} + 3\mathbf{c}$  is collinear with  $\mathbf{a}$ .

$$\therefore \qquad \mathbf{b} + 3\mathbf{c} = \mu \mathbf{a} \qquad \qquad \dots \text{(ii)}$$

Now, 
$$a+2b+6c=(a+2b)+6c=\lambda c+6c$$

$$= (\lambda + 6)\mathbf{c} \qquad \dots(iii)$$

...(i)

Also, 
$$\mathbf{a} + 2\mathbf{b} + 6\mathbf{c} = \mathbf{a} + 2(\mathbf{b} + 3\mathbf{c}) = \mathbf{a} + 2\mu\mathbf{a}$$
  
=  $(2\mu + 1)\mathbf{a}$  ...(iv)

From Eqs. (iii) and (iv), we get

$$(\lambda + 6)\mathbf{c} = (2\mu + 1)\mathbf{a}$$

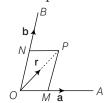

But **a** and **c** are non-zero, non-collinear vectors,

.. 
$$\lambda + 6 = 0 = 2\mu + 1$$
  
Hence,  $\mathbf{a} + 2\mathbf{b} + 6\mathbf{c} = 0$ 

# **Theorem of Coplanar Vectors**

Let **a** and **b** be two non-zero, non-collinear vectors. Then any vector **r** coplanar with **a** and **b** can be uniquely expressed as a linear combination  $x\mathbf{a} + y\mathbf{b}$ ; x and y being scalars.

**Proof** Let  $\mathbf{a}$  and  $\mathbf{b}$  be any two non-zero, non-collinear vectors and  $\mathbf{r}$  be any vector coplanar with  $\mathbf{a}$  and  $\mathbf{b}$ . We take any point O in the plane of  $\mathbf{a}$  and  $\mathbf{b}$ 

Let

$$OA = a$$
,  $OB = b$  and  $OP = r$ 

Clearly, OA, OB and OP are coplanar.

Through P, we draw lines PM and PN, parallel to OB and OA respectively meeting OA and OB at M and N respectively.

We have,  $\mathbf{OP} = \mathbf{OM} + \mathbf{MP}$ 

$$=$$
 **OM**  $+$  **ON** [::  $MP = ON$  and  $MP \mid\mid ON$ ] ...(i)

Now, **OM** and **OA** are collinear vectors

 $\mathbf{OM} = x \mathbf{OA} = x\mathbf{a}$ , where x is scalar.

Similarly,  $\mathbf{ON} = y\mathbf{OB} = y\mathbf{b}$ , where y is a scalar.

Hence, from Eq. (i),  $\mathbf{OP} = x\mathbf{a} + y\mathbf{b}$  or  $\mathbf{r} = x'\mathbf{a} + y'\mathbf{b}$ 

**Uniqueness:** If possible, let  $\mathbf{r} = x\mathbf{a} + y\mathbf{b}$  and  $\mathbf{r} = x'\mathbf{a} + y'\mathbf{b}$ 

be two different ways of representing *r*.

Then, we have 
$$x\mathbf{a} + y\mathbf{b} = x'\mathbf{a} + y'\mathbf{b}$$

$$\Rightarrow (x - x')\mathbf{a} + (y - y')\mathbf{b} = 0$$

But **a** and **b** are non-collinear vectors

$$\therefore x - x' = 0 \text{ and } y - y' = 0$$

$$\Rightarrow$$
  $x' = x \text{ and } y' = y$ 

Thus, the uniqueness in established.

# Test of Coplanarity of Three Vectors

- (i) Three vectors **a**, **b**, **c** are coplanar iff any one of them is a linear combination of the remaining two, i.e. iff  $\mathbf{a} = x\mathbf{b} + y\mathbf{c}$  where x and y are scalars.
- (ii) If three points with position vectors  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}, \ \mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$  and  $\mathbf{c} = c_1 \hat{\mathbf{i}} + c_2 \hat{\mathbf{j}} + c_3 \hat{\mathbf{k}}$  are coplanar,

then 
$$\begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = 0.$$

If vectors  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are coplanar, then there exist scalars x and y such that  $\mathbf{c} = x\mathbf{a} + y\mathbf{b}$ .

Hence, 
$$c_1 \hat{\mathbf{i}} + c_2 \hat{\mathbf{j}} + c_3 \hat{\mathbf{k}} = x(a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}})$$
  
+ $y(b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}})$ 

Now,  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  are non-coplanar and hence independent.

Then, 
$$c_1 = xa_1 + yb_1$$
,  $c_2 = xa_2 + yb_2$   
and  $c_3 = xa_3 + yb_3$ 

The above system of equations in terms of x and y is consistent. Thus,

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = 0 \text{ or } \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = 0.$$

# **Test of Coplanarity of Four Points**

- (i) To prove that four points  $A(\mathbf{a})$ ,  $B(\mathbf{b})$ ,  $C(\mathbf{c})$  and  $D(\mathbf{d})$  are coplanar, it is just sufficient to prove that vectors AB, AC and AD and coplanar.
- (ii) Four points with position vectors  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$  and  $\mathbf{d}$  are coplanar iff there exist scalars x, y, z and u not all zero such that  $x \mathbf{a} + y \mathbf{b} + z \mathbf{c} + u \mathbf{d} = 0$ , where x + y + z + u = 0.

$$\mathbf{c} = c_1 \hat{\mathbf{i}} + c_2 \hat{\mathbf{j}} + c_3 \hat{\mathbf{k}}$$

and  $\mathbf{d} = d_1 \hat{\mathbf{i}} + d_2 \hat{\mathbf{j}} + d_3 \hat{\mathbf{k}}$ 

will be coplanar, iff 
$$\begin{vmatrix} a_1 & a_2 & a_3 & 1 \\ b_1 & b_2 & b_3 & 1 \\ c_1 & c_2 & c_3 & 1 \\ d_1 & d_2 & d_3 & 1 \end{vmatrix} = 0$$

or 
$$\begin{vmatrix} d_1 - a_1 & d_2 - a_2 & d_3 - a_3 \\ b_1 - a_1 & b_2 - a_2 & b_3 - a_3 \\ c_1 - a_1 & c_2 - a_2 & c_3 - a_3 \end{vmatrix} = 0$$

# Theorem on Non-coplanar Vectors

# Theorem 1

If **a**, **b**, **c**, are three non-zero, non-coplanar vectors and x, y, z are three scalars such that

$$x\mathbf{a} + y\mathbf{b} + z\mathbf{c} = 0.$$

Then

$$x = y = z = 0.$$

**Proof** It is given that 
$$x\mathbf{a} + y\mathbf{b} + z\mathbf{c} = 0$$
 ...(i)

Suppose that  $x \neq 0$ 

Then Eq. (i) can be written as

$$x\mathbf{a} = -y\mathbf{b} - z\mathbf{c}$$

\_

$$\mathbf{a} = -\frac{y}{x}\mathbf{b} - \frac{z}{x}\mathbf{c} \qquad \dots (ii)$$

Now,  $\frac{y}{x}$  and  $\frac{z}{x}$  are scalars because x, y and z are scalars.

Thus, Eq. (ii) expresses  $\mathbf{a}$  as a linear combination of  $\mathbf{b}$  and  $\mathbf{c}$ .

Hence,  $\mathbf{a}$  is coplanar with  $\mathbf{b}$  and  $\mathbf{c}$  which is contrary to our hypothesis because  $\mathbf{a}$ , $\mathbf{b}$  and  $\mathbf{c}$  are given to be non-coplanar.

Thus, our supposition that  $x \neq 0$  is wrong.

Hence, x = 0

Similarly, we can prove that y = 0 and z = 0

# Theorem 2

If **a**,**b** and **c** are non-coplanar vectors, then any vector **r** can be uniquely expressed as a linear combination  $x\mathbf{a} + y\mathbf{b} + z\mathbf{c}$ ; x, y and z being scalars.

Any vector in space can be expressed as a linear combination of three non-coplanar vectors.

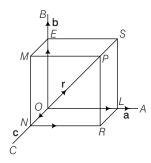

**Proof** Take any point *O*.

Let  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$  be any three non-coplanar vectors and  $\mathbf{r}$  be any vector in space.

$$OA = a$$
,  $OB = b$ ,  
 $OC = c$ ,  $OP = r$ 

Here, the three lines *OA*, *OB*, *OC* are not coplanar. Hence, they determine three different planes *BOC*, *COA* and *AOB* when taken in pairs.

Through *P*, draw planes parallel to these planes *BOC*, *COA* and *AOB* meeting *OA*, *OB* and *OC* in *L*, *E* and *N* respectively. Thus we obtain a parallelopiped with *OP* as diagonal and three coterminous edges *OL*, *OE* and *ON* along *OA*, *OB* and *OC*, respectively.

∴ **OL** is collinear with **OA**.

 $\therefore$  OL = xOA = xa, where x is a scalar.

Similarly, **OE** = y **b** and **ON** = z**c**,

where y and z are scalars.

Now, 
$$OP = OR + RP = (ON + NR) + RP$$
  
=  $ON + OL + OE$  [:  $NR = OL$  and  $RP = OE$ ]  
=  $OL + OE + ON = xa + yb + zc$ 

Thus, 
$$\mathbf{r} = x\mathbf{a} + y\mathbf{b} + z\mathbf{c}$$

Hence,  $\mathbf{r}$  can be expressed as a linear combination of  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$ .

Uniqueness If possible let

$$\mathbf{r} = x\mathbf{a} + y\mathbf{b} + z\mathbf{c}$$

. . . .

$$\mathbf{r} = x'\mathbf{a} + y'\mathbf{b} + z'\mathbf{c}$$

be two different ways of representing  $\mathbf{r}$ , then we have

$$x\mathbf{a} + y\mathbf{b} + z\mathbf{c} = x'\mathbf{a} + y'\mathbf{b} + z'\mathbf{c}$$

$$\Rightarrow (x - x')\mathbf{a} + (y - y')\mathbf{b} + (z - z')\mathbf{c} = 0$$

Now **a**, **b** and **c** are non-coplanar vectors

$$\therefore x - x' = 0, y - y' = 0 \text{ and } z - z' = 0$$

$$\Rightarrow x = x', y = y' \text{ and } z = z'$$

Hence, the uniqueness is established.

### Remark

If a, b, c are any three non-coplanar vectors in space, then

$$x_{1}\mathbf{a} + y_{1}\mathbf{b} + z_{1}\mathbf{c} = x_{2}\mathbf{a} + y_{2}\mathbf{b} + z_{2}\mathbf{c}$$

$$\Rightarrow x_{1} = x_{2}, y_{1} = y_{2}, z_{1} = z_{2}$$
**Proof**  $x_{1}\mathbf{a} + y_{1}\mathbf{b} + z_{1}\mathbf{c} = x_{2}\mathbf{a} + y_{2}\mathbf{b} + z_{2}\mathbf{c}$ 

$$\Rightarrow (x_{1} - x_{2})\mathbf{a} + (y_{1} - y_{2})\mathbf{b} + (z_{1} - z_{2})\mathbf{c} = 0$$

$$\Rightarrow x_{1} - x_{2} = 0, y_{1} - y_{2} = 0 \text{ and } z_{1} - z_{2} = 0$$

$$\Rightarrow x_{1} = x_{2}, y_{1} = y_{2} \text{ and } z_{1} = z_{2}$$

# Example 39. Check whether the given three vectors are coplanar or non-coplanar.

$$-2\hat{i}-2\hat{j}+4\hat{k}$$
,  $-2\hat{i}+4\hat{j}-2\hat{k}$ ,  $4\hat{i}-2\hat{j}-2\hat{k}$ 

**Sol.** Let 
$$\mathbf{a} = -2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$

$$\mathbf{b} = -2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$
 and  $\mathbf{c} = 4\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$ 

Now, consider

$$\begin{vmatrix} -2 & -2 & 4 \\ -2 & 4 & -2 \\ 4 & -2 & -2 \end{vmatrix} = -2(-8-4) + 2(4+8) + 4(4-16)$$

$$= 24 + 24 - 48 = 0$$

.. The vectors are coplanar.

# **Example 40.** If the vectors $4\hat{i} + 11\hat{j} + m\hat{k}$ , $7\hat{i} + 2\hat{j} + 6\hat{k}$ and $\hat{i} + 5\hat{j} + 4\hat{k}$ are coplanar, then m is equal to

(a) 38

(b) 0

(c) 10

(d) -10

**Sol.** (c) Since the three vectors are coplanar, one will be a linear combination of the other two.

$$\therefore \qquad 4\hat{\mathbf{i}} + 11\hat{\mathbf{j}} + m\hat{\mathbf{k}} = x(7\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 6\hat{\mathbf{k}}) + y(\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 4\hat{\mathbf{k}})$$

$$\Rightarrow \qquad 4 = 7x + y \qquad \dots(i)$$

$$11 = 2x + 5y \qquad \dots(ii)$$

$$m = 6x + 4y \qquad ...(iii)$$

From Eqs. (i) and (ii), we get

$$x = \frac{3}{11}$$
 and  $y = \frac{23}{11}$ 

From Eq. (iii), we get

$$m = 6 \times \frac{3}{11} + 4 \times \frac{23}{11} = 10$$

Trick Since, vectors  $4\hat{\mathbf{i}} + 11\hat{\mathbf{j}} + m\hat{\mathbf{k}}$ ,  $7\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 6\hat{\mathbf{k}}$  and  $\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$  are coplanar.

$$\begin{vmatrix} 4 & 11 & m \\ 7 & 2 & 6 \\ 1 & 5 & 4 \end{vmatrix} = 0$$

$$\Rightarrow$$
 4(8-30) - 11(28-6) + m(35-2) = 0

$$\Rightarrow \qquad -88 - 11 \times 22 + 33m = 0$$

$$\Rightarrow \qquad -8 - 22 + 3m = 0$$

$$\Rightarrow \qquad 3m = 30 \Rightarrow m = 10$$

# **■ Example 41.** If a, b and c are non-coplanar vectors, prove that 3a - 7b - 4c, 3a - 2b + c and a + b + 2c are coplanar.

**Sol.** Let 
$$\alpha = 3a - 7b - 4c$$
,  $\beta = 3a - 2b + c$ 

and 
$$\gamma = \mathbf{a} + \mathbf{b} + 2\mathbf{c}$$

Also, let 
$$\alpha = x\beta + y - \gamma$$

$$\Rightarrow 3\mathbf{a} - 7\mathbf{b} - 4\mathbf{c} = x(3\mathbf{a} - 2\mathbf{b} + \mathbf{c}) + y(\mathbf{a} + \mathbf{b} + 2\mathbf{c})$$
$$= (3x + y)\mathbf{a} + (-2x + y)\mathbf{b} + (x + 2y)\mathbf{c}$$

Since,  $\boldsymbol{a},\,\boldsymbol{b}$  and  $\boldsymbol{c}$  are non-coplanar vectors.

Therefore,

$$3x + y = 3, -2x + y = -7$$

and

$$x + 2y = -4$$

Solving first two, we find that x = 2 and y = -3. These values of x and y satisfy the third equation as well.

So, x + 2 and y = -3 is the unique solution for the above system of equation.

$$\Rightarrow$$
  $\alpha = 2\beta - 3\gamma$ 

Hence, the vectors  $\alpha$ ,  $\beta$  and  $\gamma$  are coplanar, because  $\alpha$  is uniquely written as linear combination of other two.

**Trick** For the vectors  $\alpha$ ,  $\beta$ ,  $\gamma$  to be coplanar, we must have

$$\begin{vmatrix} 3 & -7 & -4 \\ 3 & -2 & 1 \\ 1 & 1 & 2 \end{vmatrix} = 0$$
, which is true

Hence,  $\alpha$ ,  $\beta$ ,  $\gamma$  are coplanar.

# **Example 42.** The value of $\lambda$ for which the four points $2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - \hat{\mathbf{k}}$ , $\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$ , $3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$ and $\hat{\mathbf{i}} - \lambda\hat{\mathbf{j}} + 6\hat{\mathbf{k}}$ are coplanar

(a) 8

- (b) 0
- (c) -2
- (d) 6

**Sol.** (c) The given four points are coplanar.

$$\begin{vmatrix} 2 & 1 & 3 & 1 \\ 3 & 2 & 4 & \lambda \\ -1 & 3 & -2 & 6 \\ 1 & 1 & 1 & 0 \end{vmatrix} = 0$$

$$\Rightarrow \begin{vmatrix} 2 & 1 & 3 & 1 \\ 0 & 0 & 0 & -(\lambda + 2) \\ -1 & 3 & -2 & 6 \\ 1 & 1 & 1 & 1 \end{vmatrix} = 0$$

Operating  $(R_2 \rightarrow R_2 - R_1 - R_4)$ 

$$\Rightarrow -(\lambda + 2)\begin{vmatrix} 2 & 1 & 3 \\ -1 & 3 & -2 \\ 1 & 1 & 1 \end{vmatrix} = 0 \Rightarrow \lambda = -2$$

# **Example 43.** Show that the points P(a+2b+c),

 $Q(\mathbf{a} - \mathbf{b} - \mathbf{c})$ ,  $R(3\mathbf{a} + \mathbf{b} + 2\mathbf{c})$  and  $S(5\mathbf{a} + 3\mathbf{b} + 5\mathbf{c})$  are coplanar given that  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are non-coplanar.

**Sol.** To show that P, Q, R, S are coplanar, we will show that PQ, PR, PS are coplanar.

$$PQ = -3b - 2c$$

$$PR = 2a - b + c$$

$$PS = 4a + b + 4c$$

Let 
$$\mathbf{PQ} = x\mathbf{PR} + y\mathbf{PS}$$

$$\Rightarrow -3\mathbf{b} - 2\mathbf{c} = x(2\mathbf{a} - \mathbf{b} + \mathbf{c}) + y(4\mathbf{a} + \mathbf{b} + 4\mathbf{c})$$

$$\Rightarrow$$
  $-3\mathbf{b} - 2\mathbf{c} = (2x + 4y)\mathbf{a} + (-x + y)\mathbf{b} + (x + 4y)\mathbf{c}$ 

As the vectors  $\mathbf{a}, \mathbf{b}, \mathbf{c}$  are non-coplanar, we can equate their coefficients.

$$\Rightarrow$$
 0 = 2x + 4y

$$\Rightarrow$$
  $-3 = -x + y$ 

$$\Rightarrow \qquad -2 = x + 4y$$

x = 2, y = -1 is the unique solution for the above system of equations.

$$\Rightarrow$$
 PQ = 2PR - PS

**PQ**,**PR**, **PS** are coplanar because **PQ** is a linear combination of **PR** and **PS** 

 $\Rightarrow$  The points **P**, **Q**, **R**, **S** are also coplanar.

Trick For the vectors PQ, PR and PS to be coplanar, we

must have 
$$\begin{vmatrix} 0 & -3 & -2 \\ 2 & -1 & 1 \\ 4 & 1 & 4 \end{vmatrix} = 0$$
 which is true

∴ The **PQ**, **PR**, **PS** are coplanar.

Hence, the points *P*, *Q*, *R*, *S* are also coplanar.

and  $\gamma = 3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$

$$x\mathbf{a} + y\mathbf{b} + z\mathbf{c} = 0$$

i.e. 
$$x(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) + y(4\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) + z(\hat{\mathbf{i}} + \alpha\hat{\mathbf{j}} + \beta\hat{\mathbf{k}}) = 0$$

i.e. 
$$(x + 4y + z)\hat{\mathbf{i}} + (x + 3y + \alpha z)\hat{\mathbf{j}} + (x + 4y + \beta z)\hat{\mathbf{k}} = 0$$

$$\Rightarrow x + 4y + z = 0, x + 3y + \alpha z = 0, x + 4y + \beta z = 0$$

$$\Rightarrow \alpha^{2} + \beta^{2} = 2$$
For non-trivial solution 
$$\begin{vmatrix} 1 & 4 & 1 \\ 1 & 3 & \alpha \\ 1 & 4 & \beta \end{vmatrix} = 0 \Rightarrow \beta = 1$$

$$\Rightarrow (c \mid^{2} = 3 \Rightarrow 1 + \alpha^{2} + \beta^{2} = 3)$$

$$\Rightarrow \alpha^{2} = 2 - \beta^{2} = 2 - 1 = 1$$

$$\therefore \alpha = \pm 1$$

$$\Rightarrow \alpha = \pm 1$$
Trick 
$$\begin{vmatrix} c \mid = \sqrt{1 + \alpha^{2} + \beta^{2}} = \sqrt{3}$$

$$\Rightarrow \alpha^{2} + \beta^{2} = 2$$

$$\therefore \mathbf{a}, \mathbf{b} \text{ and } \mathbf{c} \text{ are linearly dependent, hence } \begin{vmatrix} 1 & 1 & 1 \\ 4 & 3 & 4 \\ 4 & \alpha & \beta \end{vmatrix} = 0$$

$$\Rightarrow \alpha^{2} = 1 \Rightarrow \alpha = \pm 1$$

# **Single Option Correct Type Questions**

- **Ex. 1** The non-zero vectors **a**,**b** and **c** are related by  $\mathbf{a} = 8\mathbf{b}$  and  $\mathbf{c} = -7\mathbf{b}$  angle between  $\mathbf{a}$  and  $\mathbf{c}$  is
- (c)  $\pi$
- (d) 0
- **Sol.** (c) a and b vectors are in the same direction, b and c are in the opposite direction.
  - $\Rightarrow$  **a** and **c** are in opposite directions.
  - $\therefore$  Angle between **a** and **c** is  $\pi$ .
- **Ex. 2** A unit vector **a** makes an angle  $\frac{\pi}{4}$  with Z-axis. If
- $\mathbf{a}+\hat{\mathbf{i}}+\hat{\mathbf{j}}$  is a unit vector, then  $\mathbf{a}$  is equal to
  - (a)  $\frac{\hat{i}}{2} + \frac{\hat{j}}{2} + \frac{\hat{k}}{\sqrt{2}}$  (b)  $\frac{\hat{i}}{2} + \frac{\hat{j}}{2} \frac{\hat{k}}{\sqrt{2}}$
  - (c)  $-\frac{\hat{\mathbf{i}}}{2} \frac{\hat{\mathbf{j}}}{2} + \frac{\hat{\mathbf{k}}}{\sqrt{2}}$  (d) None of these
- **Sol.** (c) Let  $\mathbf{a} = l \hat{\mathbf{i}} + m \hat{\mathbf{j}} + n \hat{\mathbf{k}}$ , where  $l^2 + m^2 + n^2 = 1$ .  $\mathbf{a}$  makes an angle  $\frac{\pi}{4}$  with *Z*-axis.
  - $\therefore \qquad n = \frac{1}{\sqrt{2}}, l^2 + m^2 = \frac{1}{2}$
  - $\mathbf{a} = l\,\hat{\mathbf{i}} + m\hat{\mathbf{j}} + \frac{\hat{\mathbf{k}}}{\sqrt{2}}$ 
    - $\mathbf{a} + \hat{\mathbf{i}} + \hat{\mathbf{j}} = (l+1)\hat{\mathbf{i}} + (m+1)\hat{\mathbf{j}} + \frac{\hat{\mathbf{k}}}{\sqrt{2}}$
  - Its magnitude is 1, hence  $(l + 1)^2 + (m + 1)^2 = \frac{1}{2}$
  - From Eqs. (i) and (ii), we get
    - $2lm = \frac{1}{2} \implies l = m = -\frac{1}{2}$

Hence,

- $\mathbf{a} = -\frac{\hat{\mathbf{i}}}{2} \frac{\hat{\mathbf{j}}}{2} + \frac{\hat{\mathbf{k}}}{\sqrt{2}}$
- Ex. 3 If the resultant of two forces of magnitudes P and Q acting at a point at an angle of  $60^{\circ}$  is  $\sqrt{7}Q$ , then P/Q is
  - (a) 1
- (c) 2

- **Sol.** (c)
- $R^2 = P^2 + Q^2 + 2PQ\cos\theta$
- $(\sqrt{7}Q)^2 = P^2 + Q^2 + 2PQ \cos 60^\circ$
- $7Q^2 = P^2 + Q^2 + PQ$
- $\Rightarrow P^2 + PO 6O^2 = 0$

- $P^2 + 3PO 2PO 6O^2 = 0$  $\Rightarrow$ 
  - P(P + 3Q) 2Q(P + 3Q) = 0
- (P-2O)(P+3O) = 0 $\Rightarrow$
- P 2Q = 0 or P + 3Q = 0 $\Rightarrow$

- Ex. 4 A vector a has the components 2p and 1 w.r.t. a rectangular cartesian system. This system is rotated through a certain angle about the origin in the counter clockwise sense. If with respect to a new system, a has components (p+1) and 1, then

...(i)

 $\Rightarrow$ 

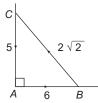

- (a) p = 0 (b) p = 1 or  $p = -\frac{1}{3}$  (c) p = -1 or  $p = \frac{1}{3}$  (d) p = 1 or p = -1
- **Sol.** (b) We have,  $\mathbf{a} = 2p\hat{\mathbf{i}} + \hat{\mathbf{j}}$

On rotation, let **b** be the vector with components (p + 1) and 1 so that.

- $\mathbf{b} = (p+1)\hat{\mathbf{i}} + \hat{\mathbf{j}}$  $|\mathbf{a}| = |\mathbf{b}| \implies a^2 = b^2$ Now,  $4p^2 + 1 = (p+1)^2 + 1 \implies 4p^2 = (p+1)^2$  $2p = \pm (p+1) \implies 3p = -1$  or p=1 $p = -\frac{1}{2}$  or p = 1
- Ex. 5 ABC is an isosceles triangle right angled at A. Forces of magnitude  $2\sqrt{2}$ , 5 and 6 act along **BC**, **CA** and **AB** respectively. The magnitude of their resultant force is
  - (a) 4
- (b) 5
- (c)  $11+2\sqrt{2}$
- (d)30
- **Sol.** (b)  $R\cos\theta = 6\cos 0^{\circ} + 2\sqrt{2}\cos(180^{\circ} B) + 5\cos 270^{\circ}$

$$R\cos\theta = 6 - 2\sqrt{2}\cos B \qquad ...(i)$$

 $R\sin\theta = 6\sin 0^{\circ} + 2\sqrt{2}\sin(180^{\circ} - B) + 5\sin 270^{\circ}$ 

$$R\sin\theta = 2\sqrt{2}\sin B - 5 \qquad \dots (ii)$$

From Eqs. (i) and (ii), we get

$$R^{2} = 36 + 8\cos^{2}B - 24\sqrt{2}\cos B + 8\sin^{2}B + 25 - 20\sqrt{2}\sin B$$
$$= 61 + 8(\cos^{2}B + \sin^{2}B) - 24\sqrt{2}\cos B - 20\sqrt{2}\sin B$$

: ABC is a right angled isosceles triangle.

i.e. 
$$\angle B = \angle C = 45^{\circ}$$

$$\therefore R^2 = 61 + 8(1) - 24\sqrt{2} \frac{1}{\sqrt{2}} - 20\sqrt{2} \cdot \frac{1}{\sqrt{2}} = 25$$

$$\therefore$$
  $R=5$ 

• **Ex. 6** A line segment has length 63 and direction ratios are 3, – 2 and 6. The components of line vector are

- (a) -27, 18, 54
- (b) 27, -18, 54
- (c) 27, -18, -54
- (d) -27, -18, -54

**Sol.** (b) Let the components of line segment on axes are x, y and z

So, 
$$x^2 + y^2 + z^2 = 63^2$$

Now, 
$$\frac{x}{3} = \frac{y}{-2} = \frac{z}{6} = k$$

$$(3k)^2 + (-2k)^2 + (6k)^2 = 63^2$$

$$k = \pm \frac{63}{7} = \pm 9$$

:. Components are (27, -18, 54) or (-27, 18, -54).

• Ex. 7 If the vectors  $6\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$ ,  $2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}}$  and  $3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$  form a triangle, then it is

- (a) right angled
- (b) obtuse angled
- (c) equilateral
- (d) isosceles

**Sol.** (b) AB = Position vectors of B Position vector of A

$$= (2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}}) - (6\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}) = -4\hat{\mathbf{i}} + 5\hat{\mathbf{j}} - 9\hat{\mathbf{k}}$$

$$\Rightarrow |\mathbf{A}\mathbf{B}| = \sqrt{16 + 25 + 81} = \sqrt{122}$$

$$\mathbf{B}\mathbf{C} = \hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$

$$\Rightarrow |\mathbf{B}\mathbf{C}| = \sqrt{1 + 9 + 16} = \sqrt{26} \text{ and } \mathbf{A}\mathbf{C} = -3\hat{\mathbf{i}} + 8\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$$

$$\Rightarrow |\mathbf{A}\mathbf{C}| = \sqrt{98}$$

Therefore,  $AB^2 = 122$ ,  $BC^2 = 26$  and  $AC^2 = 98$ 

$$\Rightarrow$$
  $AB^2 + BC^2 = 26 + 122 = 148$ 

Since,  $AC^2 < AB^2 + BC^2$ , therefore  $\Delta ABC$  is an obtuse angled triangle.

**Ex. 8** The position vectors of the points A, B and C are  $(2\hat{\mathbf{i}} + \hat{\mathbf{j}} - \hat{\mathbf{k}}), (3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}})$  and  $(\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 3\hat{\mathbf{k}})$  respectively. These points.

- (a) form an isosceles triangle
- (b) form a right angled triangle
- (c) are collinear
- (d) form a scalene triangle

**Sol.** (c) 
$$\mathbf{AB} = (3-2)\hat{\mathbf{i}} + (-2-1)\hat{\mathbf{j}} + (1+1)\hat{\mathbf{k}}$$
$$= \hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$
$$\mathbf{BC} = (1-3)\hat{\mathbf{i}} + (4+2)\hat{\mathbf{j}} + (-3-1)\hat{\mathbf{k}}$$
$$= -2\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 4\hat{\mathbf{k}}$$

$$\mathbf{CA} = (2-1)\hat{\mathbf{i}} + (1-4)\hat{\mathbf{j}} + (-1+3)\hat{\mathbf{k}}$$

$$= \hat{\mathbf{i}} - 3\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$

$$|\mathbf{AB}| = \sqrt{1+9+4} = \sqrt{14}$$

$$|\mathbf{BC}| = \sqrt{4+36+16} = \sqrt{56} = 2\sqrt{14}$$

$$|\mathbf{CA}| = \sqrt{1+9+4} = \sqrt{14}$$

So,  $|\mathbf{AB}| + |\mathbf{AC}| = |\mathbf{BC}|$  and angle between AB and BC is  $180^\circ$ . So, points A, B and C cannot form an isosceles triangle. Hence, A, B and C are collinear.

**Ex. 9** The position vector of a point C with respect to B is  $\hat{i} + \hat{j}$  and that of B with respect to A is  $\hat{i} - \hat{j}$ . The position vector of C with respect to A is

- (a) 2**î**
- (b)  $2\hat{\mathbf{j}}$
- $(c) 2\hat{j}$
- $(d) 2\hat{i}$

**Sol.** (a) Since, position vectors of a point C with respect to B is

$$\mathbf{BC} = \hat{\mathbf{i}} + \hat{\mathbf{j}} \qquad \dots (i)$$

...(ii)

Similarly,

$$\mathbf{A}\mathbf{B} = \hat{\mathbf{i}} - \hat{\mathbf{j}}$$

Now, by Eqs. (i) and (ii),

$$\mathbf{AC} = \mathbf{AB} + \mathbf{BC} = 2\hat{\mathbf{i}}$$

• **Ex. 10** In a  $\triangle ABC$ , if 2AC = 3CB, then 2OA + 3OB is equal to

- (a) 5**OC**
- (b) OC
- (c) **OC**
- (d) None of these

**Sol.** (a) 
$$2OA + 3OB = 2(OC + CA) + 3(OC + CB)$$

 $= 5\mathbf{OC} + 2\mathbf{CA} + 3\mathbf{CB} = 5\mathbf{OC} \ (\because 2\mathbf{CA} = -3\mathbf{CB})$ 

• Ex. 11 If a, b, c and d be the position vectors of the points A, B, C and D respectively, referred to same origin O such that no three of these points are collinear and

- $\mathbf{a} + \mathbf{c} = \mathbf{b} + \mathbf{d}$ , then quadrilateral ABCD is a
  - (a) square
- (b) rhombus
- (c) rectangle
- (d) parallelogram

Sol. (d) Given,

$$\mathbf{a} + \mathbf{c} = \mathbf{b} + \mathbf{d}$$

$$\Rightarrow \frac{1}{2}(\mathbf{a} + \mathbf{c}) = \frac{1}{2}(\mathbf{b} + \mathbf{d})$$

Here, mid-points of **AC** and **BD** coincide, where **AC** and **BD** are diagonals. In addition, we know that, diagonals of a parallelogram bisect each other.

Hence, quadrilateral is parallelogram.

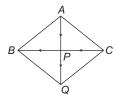

- **Ex. 12** P is a point on the side BC of the  $\triangle ABC$  and Q is a point such that PQ is the resultant of AP, PB and PC. Then, ABQC is a
  - (a) square
  - (b) rectangle
  - (c) parallelogram
  - (d) trapezium

(d)0

**Sol.** (c) 
$$AP + PB + PC = PQ$$
 or  $AP + PB = PQ + CP$ 

 $\Rightarrow$ 

$$AB = CQ$$

Hence, it is a parallelogram.

**Ex. 13** If ABCD is a parallelogram and the position vectors of A, B and C are  $\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$ ,  $\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $7\hat{\mathbf{i}} + 7\hat{\mathbf{j}} + 7\hat{\mathbf{k}}$ , then the position vector of D will be

(a) 
$$7\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$$

(b) 
$$7\hat{i} + 9\hat{i} + 11\hat{k}$$

(c) 
$$9\hat{i} + 11\hat{j} + 13\hat{k}$$

(d) 
$$8\hat{i} + 8\hat{j} + 8\hat{k}$$

**Sol.** (b) Let position vector of *D* is  $x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$ , then  $\mathbf{AB} = \mathbf{DC}$ .

$$\Rightarrow -2\hat{\mathbf{j}} - 4\hat{\mathbf{k}} = (7 - x)\hat{\mathbf{i}} + (7 - y)\hat{\mathbf{j}} + (7 - z)\hat{\mathbf{k}}$$

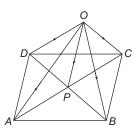

$$\Rightarrow$$
  $x = 7, y = 9 \text{ and } z = 11$ 

Hence, position vector of *D* will be  $7\hat{\mathbf{i}} + 9\hat{\mathbf{j}} + 11\hat{\mathbf{k}}$ .

• Ex. 14 P is the point of intersection of the diagonals of the parallelogram ABCD. If O is any point, then

OA + OB + OC + OD is equal to

**Sol.** (d) We know that, *P* will be the mid-point of *AC* and *BD*.

$$\therefore \qquad \mathbf{OA} + \mathbf{OC} = 2\mathbf{OP}$$

and

$$\mathbf{OB} + \mathbf{OD} = 2\mathbf{OP}$$

On adding Eqs. (i) and (ii), we get

$$OA + OB + OC + OD = 4OP$$

• **Ex. 15** If C is the middle point of AB and P is any point outside AB, then

(a) 
$$PA + PB = PC$$

(b) 
$$PA + PB = 2PC$$

(c) 
$$\mathbf{PA} + \mathbf{PB} + \mathbf{PC} = 0$$

(d) 
$$\mathbf{PA} + \mathbf{PB} + 2\mathbf{PC} = 0$$

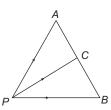

**Sol.** (b) 
$$PA + PB = (PA + AC) + (PB + BC) - (AC + BC)$$

$$= \mathbf{PC} + \mathbf{PC} - (\mathbf{AC} - \mathbf{CB}) = 2\mathbf{PC} - 0$$

(:: AC = CB)

$$\mathbf{PA} + \mathbf{PB} = 2\mathbf{PC}$$

**Ex. 16** If O be the circumcentre and O' be the orthocentre of the  $\triangle ABC$ , then O' A + O'B + O'C is equal to

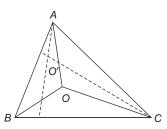

**Sol.** (b)

$$\mathbf{O'A} = \mathbf{O'O} + \mathbf{OA}$$

$$O'B = OO' + OB$$

$$O'C = O'O + OC$$

$$\Rightarrow$$
 O'A + O'B + O'C = 3O'O + OA + OB + OC

Since, 
$$OA + OB + OC = OO' = -O'O$$
  

$$\therefore O'A + O'B + O'C = 2O'O$$

Resultant = 
$$(\mathbf{AC} + \mathbf{AD} + \mathbf{AE}) + \mathbf{CB} + \mathbf{BD} + \mathbf{EB})$$
  
=  $(\mathbf{AC} + \mathbf{CB}) + (\mathbf{AD} + \mathbf{DB}) + (\mathbf{AE} + \mathbf{EB})$   
=  $\mathbf{AB} + \mathbf{AB} + \mathbf{AB} = 3\mathbf{AB}$ 

• **Ex. 18** If the vectors represented by the sides AB and BC of the regular hexagon ABCDEF be **a** and **b**, then the vector represented by **AE** will be

So,

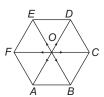

(b) 
$$\mathbf{b} - \mathbf{a}$$

(c) 
$$2a - b$$

(d) 
$$\mathbf{a} + \mathbf{b}$$

**Sol.** (a) As in figure, AB = a, BC = b,

$$AD = 2b$$
 and  $ED = a$ 

$$AE + ED = AD$$

$$\Rightarrow$$

$$AE = AD - ED = 2b - a$$

(a) 
$$\frac{\pi}{2}$$

(b) 
$$\frac{\pi}{3}$$

(c) 
$$\frac{\pi}{4}$$

(d) 
$$\frac{\pi}{c}$$

**Sol.** (b)

Let  $\theta$  be the angle between **a** and **b**. Then,  $\angle C = \pi - \theta$ .

$$\therefore \qquad \cos(\pi - \theta) = \frac{3^2 + 5^2 - 7^2}{2(3)(5)}$$

$$\therefore \qquad -\cos\theta = \frac{-1}{2}$$

$$\therefore \qquad \qquad \theta = 60^{\circ} = \frac{\pi}{3}$$

**Ex. 20** If **a** and **b** are the position vectors of A and B respectively, then the position vector of a point C on AB produced such that AC = 3AB is

(a) 
$$3a - b$$

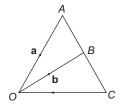

(b) 
$$3b - a$$

(c) 
$$3a - 2b$$

(d) 
$$3b - 2a$$

**Sol.** (d) Since, given that AC = 3AB. It means that point C divides AB externally.

Thus, AC : BC = 3 : 2

Hence,

$$\mathbf{OC} = \frac{3 \cdot \mathbf{b} - 2 \cdot \mathbf{a}}{3 - 2} = 3\mathbf{b} - 2\mathbf{a}$$

**Ex. 21** Let A and B be points with position vectors **a** and **b** with respect to the origin O. If the point C on OA is such that 2AC = CO, CD is parallel to OB and |CD| = 3|OB|, then **AD** is equal to

(a) 
$$3b - \frac{a}{3}$$

(b) 3**b** + 
$$\frac{a}{3}$$

(c) 
$$3b - \frac{a}{3}$$

(d) 
$$3b + \frac{a}{3}$$

**Sol.** (c) Since, OA = a, OB = b and 2AC = CO

By section formula, 
$$\mathbf{OC} = \frac{2}{3}\mathbf{a}$$

Therefore, 
$$| \mathbf{CD} | = 3 | \mathbf{OB} |$$

$$\Rightarrow$$
 CD = 3b

$$\Rightarrow OD = OC + CD = \frac{2}{3}a + 3b$$

Hence, 
$$AD = OD - OA = \frac{2}{2}a + 3b - a$$

$$\begin{array}{c} \textbf{Sol.}\ (b,\ c,\ d) \quad c+a=(b+c)+(a-b) \\ \quad a+b=(b-c)+(c+a) \\ \quad a+c=(a+b)+(c-a) \end{array}$$

So, vectors in options (b), (c) and (d) are coplanar.

• **Ex. 44** In a four-dimensional space where unit vectors along the axes are  $\hat{\bf i}$ ,  $\hat{\bf j}$ ,  $\hat{\bf k}$  and  $\hat{\bf i}$ , and  ${\bf a}_1$ ,  ${\bf a}_2$ ,  ${\bf a}_3$ ,  ${\bf a}_4$  are four non-zero vectors such that no vector can be expressed as a linear combination of others and  $(\lambda-1)({\bf a}_1-{\bf a}_2)+\mu({\bf a}_2+{\bf a}_3)+\gamma({\bf a}_3+{\bf a}_4-2{\bf a}_2)+{\bf a}_3+\delta{\bf a}_4=0$ , then (a)  $\lambda=1$  (b)  $\mu=-\frac{2}{3}$  (c)  $\gamma=\frac{2}{3}$  (d)  $\delta=\frac{1}{3}$ 

**Sol.** (a, b, d) 
$$(\lambda - 1)(\mathbf{a}_1 - \mathbf{a}_2) + \mu(\mathbf{a}_2 + \mathbf{a}_3) + \gamma(\mathbf{a}_3 + \mathbf{a}_4 - 2\mathbf{a}_2) + \mathbf{a}_3 + \delta \mathbf{a}_4 = \mathbf{0}$$
 i.e.  $(\lambda - 1)\mathbf{a}_1 + (1 - \lambda + \mu - 2\gamma)\mathbf{a}_2 + (\mu + \gamma + 1)\mathbf{a}_3 + (\gamma + \delta)\mathbf{a}_4 = \mathbf{0}$  Since,  $\mathbf{a}_1$ ,  $\mathbf{a}_2$ ,  $\mathbf{a}_3$  and  $\mathbf{a}_4$  are linearly independent, we have 
$$\lambda - 1 = 0, 1 - \lambda + \mu - 2\gamma = 0,$$
 
$$\mu + \gamma + 1 = 0 \quad \text{and} \quad \gamma + \delta = 0$$
 i.e. 
$$\lambda = 1, \mu = 2\gamma, \mu + \gamma + 1 = 0, \gamma + \delta = 0$$
 Hence,  $\lambda = 1, \mu = -\frac{2}{3}, \gamma = -\frac{1}{3}, \delta = \frac{1}{3}$

## **Statement I and II Type Questions**

**Directions** (Ex. Nos. 45-51) This section is based on **Statement** I and **Statement** II. Select the correct answer from the codes given below.

- (a) Both Statement I and Statement II are correct and Statement II is the correct explanation of Statement I
- (b) Both Statement I and Statement II are correct but Statement II is not the correct explanation of Statement I
- (c) Statement I is correct but Statement II is incorrect
- (d) Statement II is correct but Statement I is incorrect
- Ex. 45 Statement I If |a| = 3, |b| = 4 and |a + b| = 5, then |a b| = 5.

**Statement II** *The length of the diagonals of a rectangle is the same.* 

- **Sol.** (a) We have, adjacent sides of triangle  $|\mathbf{a}| = 3$ ,  $|\mathbf{b}| = 4$ The length of the diagonal is  $|\mathbf{a} + \mathbf{b}| = 5$ 
  - Since, it satisfies the Pythagoras theorem,  $\mathbf{a} \perp \mathbf{b}$
  - So, the parallelogram is a rectangle.

Hence, the length of the other diagonal is  $|\mathbf{a} - \mathbf{b}| = 5$ .

• **Ex.** 46 Statement I If  $|\mathbf{a} + \mathbf{b}| = |\mathbf{a} - \mathbf{b}|$ , then  $\mathbf{a}$  and  $\mathbf{b}$  are perpendicular to each other.

**Statement II** If the diagonals of a parallelogram are equal in magnitude, then the parallelogram is a rectangle.

**Sol.** (a)  $\mathbf{a} + \mathbf{b} = \mathbf{a} - \mathbf{b}$  are the diagonals of a parallelogram whose sides are  $\mathbf{a}$  and  $\mathbf{b}$ .

$$|\mathbf{a} + \mathbf{b}| = |\mathbf{a} - \mathbf{b}|$$

Thus, diagonals of the parallelogram have the same length. So, the parallelogram is a rectangle, i.e.  $a\perp b.$ 

• Ex. 47 Statement I If I is the incentre of  $\triangle ABC$ , then  $|\mathbf{BC}|\mathbf{IA} + |\mathbf{CA}|\mathbf{IB} + |\mathbf{AB}|\mathbf{IC} = 0$ 

**Statement II** The position vector of centroid of  $\triangle ABC$  is  $\mathbf{OA} + \mathbf{OB} + \mathbf{OC}$ 

**Sol.** (b) We know that,

OI = 
$$\frac{|CB|OA + |CA|OB + |AB|OC}{|BC| + |CA| + |AB|}$$

$$OG = \frac{OA + OB + OC}{3}$$

and

• **Ex.** 48 Statement I If  $\mathbf{u}$  and  $\mathbf{v}$  are unit vectors inclined at an angle  $\alpha$  and  $\mathbf{x}$  is a unit vector bisecting the angle

between them, then 
$$\mathbf{x} = \frac{\mathbf{u} + \mathbf{v}}{2 \sin \frac{\alpha}{2}}$$
.

**Statement II** If ABC is an isosceles triangles with AB = AC = 1, then vectors representing bisector of angle A is given by  $AB = \frac{AB + AC}{2}$ .

**Sol.** (d) We know that the unit vector along bisector of unit vectors  $\mathbf{u}$  and  $\mathbf{v}$  is  $\frac{\mathbf{u} + \mathbf{v}}{2\cos\frac{\theta}{2}}$ , where  $\theta$  is the angle between

vectors **u** and **v**.

Also, in an isosceles  $\triangle ABC$  in which

AB = AC, the median and bisector from A must be same line.

• Ex. 49 Statement I If  $\mathbf{a} = 2\hat{\mathbf{i}} + \hat{\mathbf{k}}$ ,  $\mathbf{b} = 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$  and  $\mathbf{c} = \lambda \mathbf{a} + \mu \mathbf{b}$  are coplanar, then  $\mathbf{c} = 4\mathbf{a} - \mathbf{b}$ .

**Statement II** A set vectors  $\mathbf{a}_1$ ,  $\mathbf{a}_2$ ,  $\mathbf{a}_3$ ,...,  $\mathbf{a}_n$  is said to be linearly independent, if every relation of the form  $l_1\mathbf{a}_1 + l_2\mathbf{a}_2 + l_3\mathbf{a}_3 + \ldots + l_n\mathbf{a}_n = 0$  implies that  $l_1 = l_2 = l_3 = \ldots = l_n = 0$  (scalar).

**Sol.** (b) **a**, **b** and **c** are coplanar  $\mathbf{c} = \lambda \mathbf{a} + \mu \mathbf{b} \implies \lambda = 4$  and  $\mu = -1$ 

• Ex. 50 Statement I Let  $A(\mathbf{a})$ ,  $B(\mathbf{b})$  and  $C(\mathbf{c})$  be three points such that  $\mathbf{a} = 2\hat{\mathbf{i}} + \hat{\mathbf{k}}$ ,  $\mathbf{b} = 3\hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  and  $\mathbf{c} = -\hat{\mathbf{i}} + 7\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$ . Then, OABC is a tetrahedron.

**Statement II** Let  $A(\mathbf{a})$ ,  $B(\mathbf{b})$  and  $C(\mathbf{c})$  be three points such that vectors  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are non-coplanar.

Then OABC is a tetrahedron.

 $\pmb{Sol.}$  (a) Given vectors are non-coplanar.

Hence, the answer is (a).

• Ex. 51 Statement I Let a, b, c and a be the position vectors of four points A, B, C and D and 3a - 2b + 5c - 6d = 0. Then points A, B, C and D are coplanar.

**Statement II** Three non-zero linearly dependent co-initial vectors (PQ, PR and PS) are coplanar. Then

 $PQ=\lambda PR+\mu PS,$  where  $\lambda$  and  $\mu$  are scalars.

**Sol.** (a) 
$$3\mathbf{a} - 2\mathbf{b} + 5\mathbf{c} - 6\mathbf{d} = (2\mathbf{a} - 2\mathbf{b}) + (-5\mathbf{a} + 5\mathbf{c}) + (6\mathbf{a} - 6\mathbf{d})$$
$$= -2\mathbf{A}\mathbf{B} + 5\mathbf{A}\mathbf{C} - 6\mathbf{A}\mathbf{D} = 0$$

Therefore, AB, AC and AD are linearly dependent.

Hence, by Statement II, Statement I is true.

## **Passage Based Questions**

## Passage I

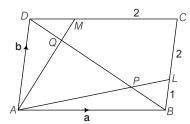

(Ex. Nos. 52 to 54)

ABCD is a parallelogram. L is a point on BC which divides BC in the ratio 1:2. AL intersects BD at P. M is a point on DC which divides DC in the ratio 1:2 and AM intersects BD in Q.

- Ex. 52 Points P divides AL in the ratio
  - (a) 1:2
- (c) 3 : 1
- (d) 2:1
- Ex. 53 Point Q divides DB in the ratio
  - (a) 1:2
- (b) 1:3
- (c) 3:1
- (d) 2:1
- **Ex. 54** PQ : DB is equal to

Sol. (Ex. Nos. 52-54)

**52.** (c)

$$\mathbf{BL} = \frac{1}{3}\mathbf{b}$$

$$\therefore \qquad AL = a + \frac{1}{3}b$$

Let  $\mathbf{AP} = \lambda \mathbf{AL}$  and *P* divides *DB* in the ratio  $\mu : 1 - \mu$ 

Then,

 $\mathbf{AP} = \lambda \mathbf{a} + \frac{\lambda}{2} \mathbf{b}$ ...(i)

Also,

 $\mathbf{AP} = \mu \mathbf{a} + (1 - \mu)\mathbf{b}$ 

...(ii)

From Eqs. (i) and (ii),

$$\lambda \mathbf{a} + \frac{\lambda}{3} \mathbf{b} = \mu \mathbf{a} + (1 - \mu) \mathbf{b}$$

*:*. and

$$\lambda = \mu$$

**53.** (b) Hence, *P* divides *AL* in the ratio 3:1 and *P* divides *DB* in the ratio 1:3 Similarly Q divides DB in the ratio 1:3.

Thus,

$$DQ = \frac{1}{4}DE$$

and

$$PB = \frac{1}{4}DB$$

**54.** (b) ::

$$PQ = \frac{1}{2}DB$$
,

i.e.

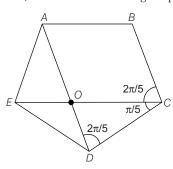

$$PQ:DB=1:2$$

## Passage II

(Ex. Nos. 55 to 56)

Let A, B, C, D, E represent vertices of a regular pentagon ABCDE. Given the position vector of these vertices be  $\mathbf{a}$ ,  $\mathbf{a}$  +  $\mathbf{b}$ ,  $\mathbf{b}$ ,  $\lambda \mathbf{a}$  and  $\lambda \mathbf{b}$  respectively.

- **Ex. 55** The ratio  $\frac{AD}{BC}$  is equal to
  - (a)  $1 \cos \frac{3\pi}{5} : \cos \frac{3\pi}{5}$  (b)  $1 + 2\cos \frac{2\pi}{5} : \cos \frac{\pi}{5}$
  - (c)  $1+2\cos\frac{\pi}{5}$ :  $2\cos\frac{\pi}{5}$  (d) None of these
- Ex. 56 AD divides EC in the ratio
  - (a)  $\cos \frac{2\pi}{5} : 1$
- (b)  $\cos \frac{3\pi}{5} : 1$
- (c) 1:  $2\cos\frac{\pi}{r}$
- Sol. (Ex. Nos. 55-56) Given ABCDE is a regular pentagon

Let position vector point *A* and *C* be **a** and **b**, respectively. AD is parallel to BC and AB is parallel to EC.

Therefore,

*AOCB* is a parallelogram and position vector of B is  $\mathbf{a} + \mathbf{b}$ . The position vectors of *E* and *D* are  $\lambda \mathbf{b}$  and  $\lambda \mathbf{a}$  respectively. Also, OA = BC = AB = OC = 1 (let)

Therefore, AOCB is rhombus.

$$\angle ABC = \angle AOC = \frac{3\pi}{5}$$

and

$$\angle OAB = \angle BCO = \pi - \frac{3\pi}{5} = \frac{2\pi}{5}$$

Further.

$$OA = AE = 1$$
 and  $OC = CD = 1$ 

Thus,  $\Delta EAO$  and  $\Delta OCD$  are isosceles.

In  $\triangle OCD$ , using sine rule we get.

$$\frac{OC}{\sin\frac{2\pi}{5}} = \frac{OD}{\sin\frac{\pi}{5}}$$

$$\Rightarrow OD = \frac{1}{2\cos\frac{\pi}{5}} = OE$$

$$\Rightarrow AD = OA + OD = 1 + \frac{1}{2\cos\frac{\pi}{5}}$$

**55.** (c) 
$$\frac{AD}{BC} = 1 + \frac{1}{2\cos\frac{\pi}{5}} = \frac{1 + 2\cos\frac{\pi}{5}}{2\cos\frac{\pi}{5}}$$

**56.** (c) 
$$\frac{OE}{OC} = \frac{1}{2\cos\frac{\pi}{5}}$$

### Passage III

(Ex. Nos. 57 to 58)

In a parallelogram OABC vectors **a**, **b**, **c** respectively, the position vectors of vertices A, B, C with reference to O as origin. A point E is taken on the side BC which divides it in the ratio of 2:1. Also, the line segment AE intersects the line bisecting the angle  $\angle AOC$  internally at point P. If CP when extended meets AB in point F, then

#### • **Ex. 57** The position vector of point P is

(a) 
$$\frac{|\mathbf{a}||\mathbf{c}|}{3|\mathbf{c}|+2|\mathbf{a}|} \left( \frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{c}}{|\mathbf{c}|} \right)$$

(b) 
$$\frac{3|\mathbf{a}||\mathbf{c}|}{3|\mathbf{c}|+2|\mathbf{a}|} \left( \frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{c}}{|\mathbf{c}|} \right)$$

$$(c) \frac{2|\mathbf{a}||\mathbf{c}|}{3|\mathbf{c}| + 2|\mathbf{a}|} \left( \frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{c}}{|\mathbf{c}|} \right)$$

(d) None of the above

#### • **Ex. 58** The ratio in which F divides AB is

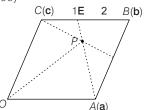

(a) 
$$\frac{2|\mathbf{a}|}{\|\mathbf{a}| - 3|\mathbf{c}|}$$

(a) 
$$\frac{2 |\mathbf{a}|}{\|\mathbf{a}\| - 3|\mathbf{c}\|}$$
 (b)  $\frac{\|\mathbf{a}\|}{\|\mathbf{a}\| - 3|\mathbf{c}\|}$  (c)  $\frac{3|\mathbf{a}|}{\|\mathbf{a}\| - 3|\mathbf{c}\|}$  (d)  $\frac{3|\mathbf{c}|}{3\|\mathbf{c}\| - \|\mathbf{a}\|}$ 

$$(c) \frac{3|\mathbf{a}|}{\|\mathbf{a}\| - 3|\mathbf{c}|}$$

$$(\mathsf{d}) \frac{3|\mathbf{c}|}{3|\mathbf{c}| - |\mathbf{a}|}$$

#### **Sol.** (Ex. Nos. 57-58)

Let the position vector of *A* and *C* be **a** and **c** respectively. Therefore,

Position vector of

$$\mathbf{B} = \mathbf{b} = \mathbf{a} + \mathbf{c} \qquad \dots (i)$$

Also, position vector of

$$E = \frac{\mathbf{b} + 2\mathbf{c}}{3} = \frac{\mathbf{a} + 3\mathbf{c}}{3} \qquad \dots \text{(ii)}$$

Now, point *P* lies on angle bisector of  $\angle AOC$ . Thus,

Position vector of point

$$P = \lambda \left( \frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{b}}{|\mathbf{b}|} \right) \qquad \dots (iii)$$

Also, let P divides EA in ration  $\mu$ : 1. Therefore, Position vector

$$= \frac{\mu \mathbf{a} + \frac{\mathbf{a} + 3\mathbf{c}}{3}}{\mu + 1} = \frac{(3\mu + 1)\mathbf{a} + 3\mathbf{c}}{3(\mu + 1)} \qquad \dots (iv)$$

Comparing Eqs. (iii) and (iv), we get

$$\lambda \left( \frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{c}}{|\mathbf{c}|} \right) = \frac{(3\mu + 1)\mathbf{a} + 3\mathbf{c}}{3(\mu + 1)}$$

$$\Rightarrow \frac{\lambda}{|\mathbf{a}|} = \frac{3\mu + 1}{3(\mu + 1)} \text{ and } \frac{\lambda}{|\mathbf{c}|} = \frac{1}{\mu + 1}$$

$$\Rightarrow \frac{3|\mathbf{c}| - |\mathbf{a}|}{3|\mathbf{a}|} = \mu$$

$$\Rightarrow \frac{\lambda}{|\mathbf{c}|} = \frac{1}{\frac{3|\mathbf{c}| - |\mathbf{a}|}{3|\mathbf{a}|} + 1} \Rightarrow \lambda = \frac{3|\mathbf{a}||\mathbf{c}|}{3|\mathbf{c}| + 2|\mathbf{a}|}$$

**57.** (b) So, position vector of P is 
$$\frac{3|\mathbf{a}||\mathbf{c}|}{3|\mathbf{c}|+2|\mathbf{a}|} \left(\frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{c}}{|\mathbf{c}|}\right)$$
.

## **58.** (d) Let F divides AB in ratio t: 1, then position vector of F is $t\mathbf{b} + \mathbf{a}$

Now, points C, P, F are collinear, Then,  $\mathbf{CF} = m\mathbf{CP}$ 

$$\Rightarrow \frac{t(\mathbf{a}+\mathbf{c})}{t+1} - \mathbf{c} = m \left\{ \frac{3|\mathbf{a}||\mathbf{c}|}{3|\mathbf{c}|+2|\mathbf{a}|} \left( \frac{\mathbf{a}}{|\mathbf{a}|} + \frac{\mathbf{c}}{|\mathbf{c}|} \right) - \mathbf{c} \right\}$$

Comparing coefficients, we get

$$\frac{t}{t+1} = m \frac{3|\mathbf{c}|}{3|\mathbf{c}| + 2|\mathbf{a}|}$$

and

$$\frac{-1}{t+1} = m \frac{|\mathbf{a}| - 3|\mathbf{c}|}{3|\mathbf{c}| + 2|\mathbf{a}|}$$

$$t = \frac{3|\mathbf{c}|}{3|\mathbf{c}| - |\mathbf{a}|}$$

• Ex. 59 In the Cartesian plane, a man starts at origin and walks a distance of 3 units of the North-East direction and reaches a point P. From P, he walks a distance of 4 units in the North-West direction to reach a point Q. Construct the parallelogram OPQR with PO and PQ as adjacent sides. Let M be the mid-point of PQ.

	Column I	Column II		
A.	The position vector of $P$ is	(p)	$\frac{3}{\sqrt{2}}(\hat{\mathbf{i}} + \hat{\mathbf{j}})$	
В.	The position vector of $R$ is	(q)	$\frac{1}{\sqrt{2}}(\hat{\mathbf{i}} + 5\hat{\mathbf{j}})$	
C.	The position vector of $M$ is	(r)	$2\sqrt{2}(-\hat{\mathbf{i}} + \hat{\mathbf{j}})$	
D.	If the line <i>OM</i> meets the diagonal <i>PR</i> in the point <i>T</i> , then <b>OT</b> equals	(s)	$\frac{\sqrt{2}}{3}(\hat{\mathbf{i}}+5\hat{\mathbf{j}})$	

**Sol.** 
$$A \rightarrow p$$
,  $B \rightarrow r$ ,  $C \rightarrow q$ ,  $D \rightarrow s$ 

(A) Let  $\hat{i}$  and  $\hat{j}$  be the unit vectors along **OX** and **OY** respectively.

Now, OP = 3 and  $\angle XOP = 45^{\circ}$  implies that

OP = 
$$(3\cos 45^{\circ})\hat{\mathbf{i}} + (3\sin 45^{\circ})\hat{\mathbf{j}} = \frac{3}{\sqrt{2}}(\hat{\mathbf{i}} + \hat{\mathbf{j}})$$

**(B)** Again,  $\angle XOR = 135^{\circ}$  and OR = 4 implies that

OR = 
$$\frac{4}{\sqrt{2}}(-\hat{i} + \hat{j}) = 2\sqrt{2}(-\hat{i} + \hat{j})$$

## **JEE Type Solved Examples:**

## **Single Integer Answer Type Questions**

- **Ex. 60** P and Q have position vectors  $\mathbf{a}$  and  $\mathbf{b}$  relative to the origin O and X, Y divide  $\mathbf{PQ}$  internally and externally respectively in the ratio 2:1. Vector  $\mathbf{XY}$  is  $\lambda \mathbf{a} + \mu \mathbf{b}$ , then the value of  $|\lambda + \mu|$  is
- **Sol.** (0) Since, X and Y divide **PQ** internally and externally in the ratio 2:1, then  $X = \frac{2\mathbf{b} + \mathbf{a}}{3}$  and  $y = 2\mathbf{b} \mathbf{a}$

 $\therefore$  XY = Position vector of *y*-Position vector of *x* 

$$=2\mathbf{b}-\mathbf{a}-\frac{2\mathbf{b}+\mathbf{a}}{3}=\frac{4\mathbf{b}}{3}-\frac{4\mathbf{a}}{3}$$

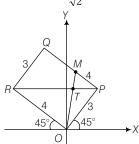

On comparing it with  $\lambda \mathbf{a} + \mu \mathbf{b}$ , we get

$$\lambda = -\frac{4}{3}$$
 and  $\mu = \frac{4}{3}$ 

$$\therefore \qquad |\lambda + \mu| = \left| \frac{-4}{3} + \frac{4}{3} \right| = 0$$

**(C)** The position vector of *Q* is given by

$$\mathbf{OP} + \mathbf{PQ} = \mathbf{OP} + \mathbf{OR} = \frac{1}{\sqrt{2}}(-\hat{\mathbf{i}} + 7\hat{\mathbf{j}})$$

$$\therefore \quad \mathbf{OM} = \frac{\left(\frac{3}{\sqrt{2}}\right)(\hat{\mathbf{i}} + \hat{\mathbf{j}}) + \left(\frac{1}{\sqrt{2}}\right)(-\hat{\mathbf{i}} + 7\hat{\mathbf{j}})}{2}$$
$$= \frac{2\hat{\mathbf{i}} + 10\hat{\mathbf{j}}}{2\sqrt{2}} = \frac{\hat{\mathbf{i}} + 5\hat{\mathbf{j}}}{\sqrt{2}}$$

**(D)** Now, 
$$PT : RT = 1 : 2$$

Therefore, 
$$\mathbf{OT} = \frac{1(\mathbf{OR}) + 2(OP)}{3}$$
$$= \frac{\left(\frac{4}{\sqrt{2}}\right)(-\hat{\mathbf{i}} + \hat{\mathbf{j}}) + 2\left[\left(\frac{3}{\sqrt{2}}\right)(\hat{\mathbf{i}} + \hat{\mathbf{j}})\right]}{3}$$
$$= \frac{\sqrt{2}}{2}(\hat{\mathbf{i}} + 5\hat{\mathbf{j}})$$

• Ex. 61 If A(1, -1, -3), B(2, 1, -2) and C(-5, 2, -6) are the position vectors of the vertices of  $\triangle ABC$ . The length of the bisector of its internal angle at A is  $\frac{\lambda\sqrt{10}}{4}$ , then value of  $\lambda$  is

**Sol.** (3) We have, 
$$AB = \hat{i} + 2\hat{j} + \hat{k}$$
,  $AC = -6\hat{i} + 3\hat{j} - 3\hat{k}$ 

$$\Rightarrow$$
  $|\mathbf{AB}| = \sqrt{6}$  and  $|\mathbf{AC}| = 3\sqrt{6}$ 

Clearly, point D divides BC in the ratio AB:AC, i.e. 1:3

$$\therefore \text{Position vector of } D = \frac{(-5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 6\hat{\mathbf{k}}) + 3(2\hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}})}{1 + 3}$$

$$=\frac{1}{4}(\hat{\mathbf{i}}+5\hat{\mathbf{j}}-12\hat{\mathbf{k}})$$

$$\therefore \quad \mathbf{AD} = \frac{1}{4}(\hat{\mathbf{i}} + 5\hat{\mathbf{j}} - 12\hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}} - 3\hat{\mathbf{k}}) = \frac{3}{4}(-\hat{\mathbf{i}} + 3\hat{\mathbf{j}})$$

$$\Rightarrow$$
  $|\mathbf{AD}| = AD = \frac{3}{4}\sqrt{10}$ 

$$\lambda = 3$$

- **Ex. 62** Let ABC be a triangle whose centroid is G, orthocentre is H and circumcentre is the origin 'O'. If D is any point in the plane of the triangle such that no three of O, A, C and D are collinear satisfying the relation
- $AD + BD + CH + 3HG = \lambda HD$ , then what is the value of the scalar ' $\Delta$ '

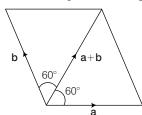

**Sol.** LHS = 
$$\mathbf{d} - \mathbf{a} + \mathbf{d} - \mathbf{b} + \mathbf{h} - \mathbf{c} + 3(\mathbf{g} - \mathbf{h})$$
  
=  $2\mathbf{d} - (\mathbf{a} + \mathbf{b} + \mathbf{c}) + 3\frac{(\mathbf{a} + \mathbf{b} + \mathbf{c})}{3} - 2\mathbf{h}$   
=  $2\mathbf{d} - 2\mathbf{h} = 2(\mathbf{d} - \mathbf{h}) = 2\mathbf{H}\mathbf{D} \Rightarrow \lambda = 2$ 

- Ex. 63 Let a, b and c be unit vectors such that
- $\mathbf{a} + \mathbf{b} \mathbf{c} = 0$ . If the area of triangle formed by vectors  $\mathbf{a}$  and  $\mathbf{b}$  is A, then what is the value of  $16A^2$ ?

**Sol.** (3) Given 
$$\mathbf{a} + \mathbf{b} = \mathbf{c}$$

Now, vector  $\mathbf{c}$  is along the diagonal of the parallelogram which has adjacent side vectors  $\mathbf{a}$  and  $\mathbf{b}$ . Since,  $\mathbf{c}$  is also a unit vector, triangle formed by vectors  $\mathbf{a}$  and  $\mathbf{b}$  is an equilateral triangle.

Then, Area of triangle 
$$=\frac{\sqrt{3}}{4} \implies A^2 = \frac{3}{10} \implies 16A^2 = 3$$

- **Ex. 64** Find the least positive integral value of x for which the angle between vectors  $\mathbf{a} = x\hat{\mathbf{i}} 3\hat{\mathbf{j}} \hat{\mathbf{k}}$  and  $\mathbf{b} = 2x\hat{\mathbf{i}} + x\hat{\mathbf{j}} \hat{\mathbf{k}}$  is acute.
- **Sol.** (2) Let  $\mathbf{a} = x\hat{\mathbf{i}} 3\hat{\mathbf{j}} \hat{\mathbf{k}}$  and  $\mathbf{b} = 2x\hat{\mathbf{i}} + x\hat{\mathbf{j}} \hat{\mathbf{k}}$  be the adjacent sides of the parallelogram.

Now angle between 
$$\mathbf{a}$$
 and  $\mathbf{b}$  is acute, i.e.  $|\mathbf{a} + \mathbf{b}| > |\mathbf{a} - \mathbf{b}|$ 

$$\Rightarrow \left| 3x\hat{\mathbf{i}} + (x-3)\hat{\mathbf{j}} - 2\hat{\mathbf{k}} \right|^2 > \left| -x\hat{\mathbf{i}} - (x+3)\hat{\mathbf{j}} \right|^2$$

or 
$$9x^2 + (x-3)^2 + 4 > x^2 + (x+3)^3$$

or 
$$8x^2 - 12x + 4 > 0$$
 or  $2x^2 - 3x + 1 > 0$ 

or 
$$(2x-1)(x-1) > 0 \implies x < \frac{1}{2} \text{ or } x > 1$$

Hence, the least positive integral value is 2.

## **Subjective Type Questions**

• Ex. 66 A particle in equilibrium is subjected to four forces

$$\mathbf{F}_1 = -10\hat{\mathbf{k}}, \qquad \mathbf{F}_2 = u\left(\frac{4}{13}\hat{\mathbf{i}} - \frac{12}{13}\hat{\mathbf{j}} + \frac{3}{13}\hat{\mathbf{k}}\right)$$

$$\mathbf{F}_3 = v \left( -\frac{4}{13}\hat{\mathbf{i}} - \frac{12}{13}\hat{\mathbf{j}} + \frac{3}{13}\hat{\mathbf{k}} \right)$$

and 
$$\mathbf{F}_4 = w(\cos\theta \,\hat{\mathbf{i}} + \sin\theta \,\hat{\mathbf{j}})$$

Find the values of u, v and w in terms of  $\theta$ .

**Sol.** Since, the particle is in equilibrium.

$$\begin{split} \mathbf{F}_{1} + \mathbf{F}_{2} + \mathbf{F}_{3} + \mathbf{F}_{4} &= 0 \\ -10\hat{\mathbf{k}} + u \bigg( \frac{4}{13}\hat{\mathbf{i}} - \frac{12}{13}\hat{\mathbf{j}} + \frac{3}{13}\hat{\mathbf{k}} \bigg) + v \bigg( -\frac{4}{13}\hat{\mathbf{i}} - \frac{12}{13}\hat{\mathbf{j}} + \frac{3}{13}\hat{\mathbf{k}} \bigg) \\ &\quad + w(\cos\theta\hat{\mathbf{i}} + \sin\theta\hat{\mathbf{j}}) = 0 \\ \Rightarrow \bigg( \frac{4u}{13} - \frac{4v}{13} + w\cos\theta \bigg) \hat{\mathbf{i}} + \bigg( \frac{-12}{13}u - \frac{12}{13}v + w\sin\theta \bigg) \hat{\mathbf{j}} \\ &\quad + \bigg( \frac{3}{13}u + \frac{3}{13}v - 10 \bigg) \hat{\mathbf{k}} = 0 \end{split}$$

$$\Rightarrow \frac{4u}{13} - \frac{4v}{13} + w\cos\theta = 0 \qquad \dots (i)$$

$$-\frac{12}{13}u - \frac{12}{13}v + w\sin\theta = 0 \qquad ...(ii)$$

$$\frac{3}{13}u + \frac{3}{13}v - 10 = 0 \qquad ...(iii)$$

From Eq. (iii), we get 
$$u + v = \frac{130}{3}$$

From Eq. (ii), we get

$$-\frac{12}{13}(u+v) + w\sin\theta = 0$$

$$\Rightarrow \qquad -\frac{12}{13} \left( \frac{130}{3} \right) + w \sin \theta = 0$$

$$\Rightarrow \qquad \qquad w = \frac{40}{\sin \theta} = 40 \csc \theta$$

On substituting the value of w in Eqs. (i) and (ii), we get

$$u - v = -130 \cot \theta$$

and 
$$u + v = \frac{130}{3}$$

On solving, we get

$$u + \frac{65}{3} - 65 \cot \theta$$

$$v + \frac{65}{3} + 65 \cot \theta \text{ and } w = 40 \csc \theta$$

**Ex. 67** Find all values of ' $\lambda$ ' such that  $x, y, z \neq (0,0,0)$  and  $(\hat{\mathbf{i}} + \hat{\mathbf{j}} + 3\hat{\mathbf{k}}) x + (3\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + \hat{\mathbf{k}}) y + (-4\hat{\mathbf{i}} + 5\hat{\mathbf{j}}) z$  =  $\lambda(x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}})$ , where  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  are unit vectors along the coordinate axes.

On comparing the coefficients of  $\hat{i}$ ,  $\hat{j}$  and  $\hat{k}$ , we get

$$\Rightarrow (1 - \lambda)x + 3y - 4z = 0 \qquad ...(i)$$

$$x - 3y + 5z = \lambda y$$

$$\Rightarrow x - (3 + \lambda)y + 5z = 0 \qquad ...(ii)$$

$$3x + y = \lambda z$$

 $\Rightarrow$  3 $x+y-\lambda z=0$  . The Eqs. (i), (ii) and (iii) will have a non-trivial solution, if

$$\begin{vmatrix} 1 - \lambda & 3 & -4 \\ 1 & -(3+\lambda) & 5 \\ 3 & 1 & -\lambda \end{vmatrix} = 0$$

$$[\therefore (x, y, z) \neq (0, 0, 0) \therefore \Delta = 0]$$

$$\Rightarrow (1 - \lambda)\{\lambda(3 + \lambda) - 5\} - 3\{-\lambda - 15\} - 4\{1 + 3(\lambda + 3)\} = 0$$

$$\Rightarrow (1 - \lambda)\{\lambda^2 + 3\lambda - 5\} - 3\{-\lambda - 15\} - 4\{3\lambda + 10\} = 0$$

$$\Rightarrow \lambda^3 + 2\lambda^2 + \lambda = 0$$

$$\Rightarrow \lambda(\lambda^2 + 2\lambda + 1) = 0$$

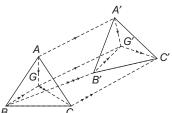

$$\Rightarrow \lambda(\lambda + 1)^2 = 0$$

$$\therefore \lambda = 0 \text{ or } \lambda = -1$$

**■ Ex. 68** If G is the centroid of the  $\triangle ABC$  and if G' is the centroid of another  $\triangle A'B'C'$ , then prove that AA' + BB' + CC' = 3GG'.

Sol. Here,

G is centroid of  $\Delta ABC$  and G' is centroid of  $\Delta A'\,B'\,C',$  shown as in figure.

Clearly, 
$$AA' = AG + GG' + G'A' \qquad \text{(polygon law)}$$
 
$$BB' = BG + GG' + G'B'$$
 
$$CC' = CG + CG' + G'C'$$

On adding these

AA' + BB' + CC' = 3GG' + (AG + BG + CG)  
+(G'A' + G'B' + G'C')  
= 3GG' + (AG + 2DG) + (G'A' + 2G'D')  
(using AD and A'D' as the medians of 
$$\triangle ABC$$
 and  $\triangle A'B'C'$ , respectively)  
= 3GG' + (AG + GA) + G'A' + A'G'  
= 3GG' + O + O  
 $\therefore$  AA' + BB' + CC' = 3GG'

We know by triangle law

$$AA' = OA' - OA$$

$$BB' = OB' - OB$$

$$CC' = OC' - OC$$

$$\Rightarrow AA' + BB' + CC' = (OA' + OB' + OC')$$

$$|\mathbf{A} + \mathbf{B}|^2 \le (1+k)|\mathbf{A}|^2 \left(1 + \frac{1}{k}\right)|\mathbf{B}|^2$$

(since, Arithmetic mean  $\geq$  Geometric mean)

So, 
$$(1 + k)|\mathbf{A}|^2 + \left(1 + \frac{1}{k}\right)|\mathbf{B}|^2 \ge |\mathbf{A}|^2 + |\mathbf{B}|^2 + 2|\mathbf{A}| \cdot |\mathbf{B}|$$

which shows that c and a have the same direction.

And 
$$\mathbf{c} = \frac{13}{11}\mathbf{a}$$
  
 $\Rightarrow |\mathbf{c}| = \frac{13}{11}|\mathbf{a}| \Rightarrow |\mathbf{c}| > |\mathbf{a}|$ 

(ii) We have,

$$\Rightarrow 1 - \frac{BA}{BF} = 1 - \frac{1}{k} \Rightarrow \frac{AF}{BF} = \frac{k-1}{k} \qquad ...(ii)$$

 $\mathbf{B}(t) = g_1(t)\hat{\mathbf{i}} + g_2(t)\hat{\mathbf{j}} t \in [0,1]$ , where  $f_1$ ,  $f_2$ ,  $g_1$  and  $g_2$  are continuous functions. Then show that  $\mathbf{A}(t)$  and  $\mathbf{B}(t)$  are parallel for some t.

**Sol.** If 
$$\mathbf{A}(t)$$
 and  $\mathbf{B}(t)$  are non-zero vectors for all  $t$  and  $\mathbf{A}(0) = 2\hat{\mathbf{i}} + 3\hat{\mathbf{j}}$ ,  $\mathbf{A}(1) = 6\hat{\mathbf{i}} + 2\hat{\mathbf{j}}$ ,  $\mathbf{B}(0) = 3\hat{\mathbf{i}} + 2\hat{\mathbf{j}}$ , and  $\mathbf{B}(1) = 2\hat{\mathbf{i}} + 6\hat{\mathbf{j}}$ .

In order to prove that  $\mathbf{A}(t)$  and  $\mathbf{B}(t)$  are parallel vectors for some values of t. It is sufficient to show that  $\mathbf{A}(t) = \lambda \mathbf{B}(t)$  for some  $\lambda$ .

$$\iff \{f_1(t)\hat{\mathbf{i}} + f_2(t)\hat{\mathbf{j}}\} = \lambda \{g_1(t)\hat{\mathbf{i}} + g_2(t)\hat{\mathbf{j}}\}\$$

$$\Leftrightarrow$$
  $f_1(t) = \lambda g_1 t \text{ and } f_2(t) = \lambda g_2(t)$ 

$$\Leftrightarrow \frac{f_1(t)}{f_2(t)} = \frac{g_1(t)}{g_2(t)}$$

$$\Leftrightarrow \qquad f_1(t)g_2(t) - f_2(t)g_1t = 0 \qquad \text{for some } t \in [0, 1]$$

Let 
$$f(t) = f_1(t)g_2(t) - f_2(t)g_1(t), t \in [0, 1]$$

Since,  $f_1$ ,  $f_2$ ,  $g_1$  and  $g_2$  are continuous functions.

 $\therefore F(t)$  is also a continuous function.

Also, 
$$f(0) = f_1(0)g_2(0) - g_1(0)f_2(0)$$

$$= 2 \times 2 - 3 \times 3 = 4 - 9 = -5 < 0$$

and 
$$f(1) = f_1(1)g_2(1) - g_1(1)f_2(1)$$

$$= 6 \times 6 - 2 \times 2 = 32 > 0$$

Thus, F(t) is a continuous function on [0, 1] such that  $F(0) \cdot F(1) < 0.$ 

:. By intermediate value theorem, there exists some  $t \in (0, 1)$ such that

$$f(t) = 0$$

• Ex. 77 If the vectors  $x\hat{i} + \hat{j} + \hat{k}$ ,  $\hat{i} + y\hat{j} + \hat{k}$  and  $\hat{i} + \hat{j} + z\hat{k}$ are coplanar where,  $x \neq 1$ ,  $y \neq 1$  and  $z \neq 1$ , then prove that  $\frac{1}{1-x} + \frac{1}{1-y} + \frac{1}{1-z} = 1$ 

**Sol.** The vectors are coplanar, if we can find two scalars  $\lambda$  and  $\mu$ 

$$(x\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) = \lambda(\hat{\mathbf{i}} + y\hat{\mathbf{j}} + \hat{\mathbf{k}}) + \mu(\hat{\mathbf{i}} + \hat{\mathbf{j}} + z\hat{\mathbf{k}})$$

$$\Rightarrow$$
  $x = \lambda + \mu, 1 = \lambda y + \mu, 1 = \lambda + \mu z$ 

$$\Rightarrow \qquad x = \lambda + \mu, \, y = \frac{1 - \mu}{\lambda}, \, z = \frac{1 - \lambda}{\mu}$$

$$\Rightarrow 1 - x = 1 - \lambda - \mu, 1 - y = \frac{\lambda - 1 + \mu}{\lambda},$$

$$1-z=\frac{\mu-1+\lambda}{\mu}$$

$$\therefore \frac{1}{1-x} + \frac{1}{1-y} + \frac{1}{1-z} = \frac{1}{1-\lambda-\mu} + \frac{\lambda}{\lambda+\mu-1} + \frac{\mu}{\lambda+\mu-1}$$
$$= \frac{-1+\lambda+\mu}{\lambda+\mu-1} = 1$$

$$\therefore \frac{1}{1-x} + \frac{1}{1-y} + \frac{1}{1-z} = 1$$

#### Aliter

Thus, above problem could also be solved as

$$\begin{vmatrix} x & 1 & 1 \\ 1 & y & 1 \\ 1 & 1 & z \end{vmatrix} = 0 \implies \begin{vmatrix} x-1 & 0 & 1-z \\ 0 & y-1 & 1-z \\ 1 & 1 & z \end{vmatrix} = 0$$

(using  $R_1 \rightarrow R_1 - R_3$  and  $R_2 \rightarrow R_2 - R_3$ )

$$\Rightarrow (x-1)(y-1)(z-1)\begin{vmatrix} 1 & 0 & -1 \\ 0 & 1 & -1 \\ -1 & -1 & -z \\ 1-x & 1-y & 1-z \end{vmatrix} = 0$$

$$\left(\text{using } R_1 \to \frac{1}{x-1} R_1, R_2 \to \frac{1}{y-1} R_2, R_3 \to \frac{1}{z-1} R_3\right)$$
$$-\frac{1}{(1-x)} (1) + \frac{1}{(1-y)} (-1) - \frac{z}{(1-z)} (1) = 0$$

$$\Rightarrow -\frac{1}{(1-x)}(1) + \frac{1}{(1-y)}(-1) - \frac{1}{(1-z)}(1) = 0$$
(expanding along  $R_3$ )

$$\Rightarrow \frac{-1}{(1-x)} - \frac{1}{(1-y)} + \frac{(1-z)-1}{(1-z)} = 0$$

$$\Rightarrow \frac{1}{1-x} + \frac{1}{1-y} + \frac{1}{1-z} = 1$$

**Ex. 78** If  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  be any three non-coplanar vectors, then prove that the points  $l_1\mathbf{a} + m_1\mathbf{b} + n_1\mathbf{c}$ ,  $l_2\mathbf{a} + m_2\mathbf{b} + n_2\mathbf{c}$ ,  $l_3$ **a** +  $m_3$ **b** +  $n_3$ **c** and  $l_4$ **a** +  $m_4$ **b** +  $n_4$ **c** are coplanar, if

$$\begin{vmatrix} l_1 & m_1 & n_1 & 1 \\ l_2 & m_2 & n_2 & 1 \\ l_3 & m_3 & n_3 & 1 \\ l_4 & m_4 & n_4 & 1 \end{vmatrix} = 0$$

**Sol.** We know that, four points having position vectors, **a**, **b**, **c** and  $\mathbf{d}$  are coplanar, if there exists scalars x, y, z and t such that

$$x\mathbf{a} + y\mathbf{b} + z\mathbf{c} + t\mathbf{d} = 0$$
 where,  $x + y + z + t = 0$ 

So, the given points will be coplanar, if there exists scalars x, y, z and t such that

$$x(l_1\mathbf{a} + m_1\mathbf{b} + n_1\mathbf{c}) + y(l_2\mathbf{a} + m_2\mathbf{b} + n_2\mathbf{c}) + z(l_3\mathbf{a} + m_3\mathbf{b} + n_3\mathbf{c}) + t(l_4\mathbf{a} + m_4\mathbf{b} + n_4\mathbf{c}) = 0$$

where, x + y + z + t = 0

$$\Rightarrow (l_1x + l_2y + l_3z + l_4t)\mathbf{a} + (m_1x + m_2y + m_3z + m_4t)\mathbf{b} + (n_1x + n_2y + n_3z + n_4t)\mathbf{c} = 0$$

where, 
$$x + y + z + t = 0$$

$$l_1x + l_2y + l_3z + l_4t = 0$$
 ...(i)

$$m_1x + m_2y + m_3z + m_4t = 0$$
 ...(ii)

$$n_1 x + n_2 y + n_3 z + n_4 t = 0$$
 ...(iii)

and 
$$x + y + z + t = 0$$
 ...(iv)

Eliminating x, y, z and t from above equations, we get

$$\begin{vmatrix} l_1 & l_2 & l_3 & l_4 \\ m_1 & m_2 & m_3 & m_4 \\ n_1 & n_2 & n_3 & n_4 \\ 1 & 1 & 1 & 1 \end{vmatrix} = 0$$

• Ex. 79 If  $\mathbf{r}_1$ ,  $\mathbf{r}_2$  and  $\mathbf{r}_3$  are the position vectors of three collinear points and scalars l and m exists such that  $\mathbf{r}_3 = l \mathbf{r}_1 + m \mathbf{r}_2$ , then show that l + m = 1.

**Sol.** Let A, B and C be the three points whose position vectors referred to O are  $\mathbf{r}_1$ ,  $\mathbf{r}_2$  and  $\mathbf{r}_3$ , respectively.

$$AB = OB - OA = r_2 - r_1$$
$$BC = OC - OB = r_3 - r_2$$

Now, if *A*, *B* and *C* are collinear points, then **AB** and **AC** are in the same line and  $\mathbf{BC} = \lambda$  (**AC**)

$$\Rightarrow \qquad (\mathbf{r}_3 - \mathbf{r}_2) = \lambda(\mathbf{r}_2 - \mathbf{r}_1)$$

$$\Rightarrow \qquad \mathbf{r}_3 = -\lambda \mathbf{r}_1 + (\lambda + 1) \mathbf{r}_2$$

$$\Rightarrow \qquad \mathbf{r}_3 = -\lambda \mathbf{r}_1 + m\mathbf{r}_2$$
where,
$$l = -\lambda \text{ and } m = \lambda + 1$$

$$\Rightarrow \qquad l + m = -\lambda + (\lambda + 1) = 1$$

• Ex. 80 Show that points with position vectors  $\mathbf{a} - 2\mathbf{b} + 3\mathbf{c}$ ,  $-2\mathbf{a} + 3\mathbf{b} - \mathbf{c}$  and  $4\mathbf{a} - 7\mathbf{b} + 7\mathbf{c}$  are collinear. It is given that vectors  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  and non-coplanar.

**Sol.** The three points are collinear, if we can find  $\lambda_1,\,\lambda_2$  and  $\lambda_3,\,$  such that

$$\lambda_1 (\mathbf{a} - 2\mathbf{b} + 3\mathbf{c}) + \lambda_2 (-2\mathbf{a} + 3\mathbf{b} - \mathbf{c}) + \lambda_3$$

$$(4\mathbf{a} - 7\mathbf{b} + 7\mathbf{c}) = 0 \text{ with } \lambda_1 + \lambda_2 + \lambda_3 = 0$$

On equating the coefficients  $\boldsymbol{a},\,\boldsymbol{b}$  and  $\boldsymbol{c}$  separately to zero, we get  $\lambda_1-2\lambda_2+4\lambda_3=0,-2\lambda_1+3\lambda_2-7\lambda_3=0$  and  $3\lambda_1-\lambda_2+7\lambda_3=0$ 

On solving we get 
$$\lambda_1 = -2, \lambda_2 = 1, \lambda_3 = 1$$

So that, 
$$\lambda_1 + \lambda_2 + \lambda_3 = 0$$

Hence, the given vectors are collinear.

# Solutions

**1.** 
$$\mathbf{a} + \mathbf{b} + \mathbf{c} = (3 + 2 - 1)\hat{\mathbf{i}} + (-2 - 4 + 2)\hat{\mathbf{j}} + (1 - 3 + 2)\hat{\mathbf{k}}$$
  
=  $4\hat{\mathbf{i}} - 4\hat{\mathbf{j}}$ 

**2.** Let **b** should be added, then  $\mathbf{a} + \mathbf{b} = \hat{\mathbf{i}}$ 

$$\Rightarrow \mathbf{b} = \hat{\mathbf{i}} - \mathbf{a} = \hat{\mathbf{i}} - (3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 2\hat{\mathbf{k}})$$
$$= -2\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

3. 
$$|\mathbf{a} + \mathbf{b}| = |3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 12\hat{\mathbf{k}}|$$
  
=  $|\sqrt{3^2 + 4^2 + (12)^2}| = 13$ 

**4.** 
$$\mathbf{a} + \mathbf{b} = 4\hat{\mathbf{i}} + 4\hat{\mathbf{j}}$$
,

Therefore, unit vector = 
$$\frac{4(\hat{\mathbf{i}} + \hat{\mathbf{j}})}{\sqrt{32}} = \frac{\hat{\mathbf{i}} + \hat{\mathbf{j}}}{\sqrt{2}}$$

**5.** Resultant vector =  $(2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}}) + (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})$ 

$$=3\hat{\mathbf{i}}+6\hat{\mathbf{j}}-2\hat{\mathbf{k}}$$

Unit vector = 
$$\frac{3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}}}{\sqrt{9 + 36 + 4}} = \frac{1}{7}(3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}})$$

6. 
$$R = 3\hat{i} + 5\hat{j} + 4\hat{k}$$

$$\Rightarrow \qquad \mathbf{R} = \frac{3\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 4\hat{\mathbf{k}}}{5\sqrt{2}}$$

**7.**  $\mathbf{a} + \mathbf{b} = 3\hat{\mathbf{i}} + 9\hat{\mathbf{j}} = 3(\hat{\mathbf{i}} + 3\hat{\mathbf{j}})$ . Hence, it is parallel to (1, 3).

$$8. \mathbf{AB} + \mathbf{BC} + \mathbf{CA} = 0$$

$$\Rightarrow$$
  $\mathbf{a} + \mathbf{b} - \mathbf{c} = 0$ 

**9.** Unit vector parallel to 
$$\mathbf{OA} = \frac{4\hat{\mathbf{i}} + 5\hat{\mathbf{j}}}{\sqrt{16 + 25}} = \frac{1}{\sqrt{41}} (4\hat{\mathbf{i}} + 5\hat{\mathbf{j}})$$

**10.** OA = 
$$\hat{i} + 2\hat{j} - \hat{k}$$
, OB =  $\hat{i} + \hat{j} + \hat{k}$ 

and 
$$\mathbf{OC} = 2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

Position vector of B w.r.t origin at A at

$$\mathbf{AB} = \mathbf{OB} - \mathbf{OA} = -\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

Position vector of *C* w.r.t. origin at *A* is

$$AC = OC - OA = \hat{\mathbf{i}} + \hat{\mathbf{j}} + 3\hat{\mathbf{k}}$$

**11.** 
$$7 = \sqrt{(5+1)^2 + (4-2)^2 + (a+2)^2}$$

$$\Rightarrow$$
  $a+2=\pm 3 \Rightarrow a=-5, 1$ 

**12.** AB = CX  $\Rightarrow \hat{j} - \hat{i}$  = position vector of point  $X - \hat{k}$ 

 $\therefore$  Position vector of point  $X = -\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$ 

**13.** 
$$\mathbf{AB} = (6-2)\hat{\mathbf{i}} + (-3+9)\hat{\mathbf{j}} + (8+4)\hat{\mathbf{k}}$$

$$=4\hat{\mathbf{i}}+6\hat{\mathbf{j}}+12\hat{\mathbf{k}}$$

$$|\mathbf{AB}| = \sqrt{16 + 25 + 144} = 14$$

**14.** PQ = 
$$(5-1)\hat{\mathbf{i}} + (-2-3)\hat{\mathbf{j}} + (4+7)\hat{\mathbf{k}}$$

$$=4\hat{\mathbf{i}}-5\hat{\mathbf{j}}+11\hat{\mathbf{k}}$$

$$|\mathbf{PO}| = \sqrt{16 + 25 + 121} = \sqrt{162}$$

**15.** 
$$PQ = QQ - QP = 4\hat{i} - 5\hat{j} + 11\hat{k}$$

$$\therefore \frac{PQ}{|PO|} = \frac{4}{\sqrt{162}} \hat{\mathbf{i}} - \frac{5}{\sqrt{162}} \hat{\mathbf{j}} + \frac{11}{\sqrt{162}} \hat{\mathbf{k}}$$

 $\therefore$  cos  $\gamma = \frac{11}{\sqrt{162}}$ , where  $\gamma$  is the angle of **PQ** with Z-axis.

**16.** 
$$AB = 4\hat{i} - 5\hat{j} + 11\hat{k}$$

Direction cosine along Y-axis =  $\frac{-5}{\sqrt{16+25+121}} = \frac{-5}{\sqrt{162}}$ 

**17.** 
$$\frac{3}{\sqrt{3^2+4^2+5^2}} = \frac{3}{\sqrt{50}}$$

**18.** Vector  $\mathbf{A} = 3\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$ . We know that, direction cosines of

$$\mathbf{A} = \frac{3}{\sqrt{3^2 + 4^2 + 5^2}}, \frac{-4}{\sqrt{3^2 + 4^2 + 5^2}}, \frac{5}{\sqrt{3^2 + 4^2 + 5^2}}$$
$$= \frac{3}{5\sqrt{2}}, \frac{-4}{5\sqrt{2}}, \frac{1}{\sqrt{2}}$$

**19.** Here. 
$$\mathbf{OA} = 2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$

$$\mathbf{OB} = 3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

and 
$$\mathbf{OC} = 4\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$$

So, 
$$\mathbf{A}\mathbf{B} = \hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}}, \mathbf{B}\mathbf{C} = \hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}, \mathbf{C}\mathbf{A} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} - \hat{\mathbf{k}}$$

Clearly, 
$$|AB| = |BC| = |CA| = \sqrt{6}$$

So, these points are vertices of an equilateral triangle.

**20.** Given, position vectors of A, B and C are  $7\hat{\mathbf{j}} + 10\hat{\mathbf{k}}$ ,

$$-\hat{\mathbf{i}} + 6\hat{\mathbf{j}} + 6\hat{\mathbf{k}}$$
 and  $-4\hat{\mathbf{i}} + 9\hat{\mathbf{j}} + 6\hat{\mathbf{k}}$ , respectively.

$$\therefore |\mathbf{A}\mathbf{B}| = |-\hat{\mathbf{i}} - \hat{\mathbf{j}} - 4\hat{\mathbf{k}}| = \sqrt{18}$$

$$|\mathbf{BC}| = |-3\hat{\mathbf{i}} + 3\hat{\mathbf{j}}| = \sqrt{18}$$

$$|\mathbf{AC}| = |-4\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 4\hat{\mathbf{k}}| = \sqrt{36}$$

Clearly, AB = BC and  $(AC)^{2} = (AB)^{2} + (BC)^{2}$ 

Hence, triangle is right angled isosceles.

**24.** Position vectors of the points which divides internally is

$$\frac{3(2\mathbf{a} - 3\mathbf{b}) + 2(3\mathbf{a} - 2\mathbf{b})}{5} = \frac{12\mathbf{a} - 13\mathbf{b}}{5}$$

**25.** Coordinate of *C* is 
$$\left(\frac{2-4}{2}, \frac{-1+3}{2}\right) = (-1, 1)$$

$$\therefore \qquad \qquad \mathbf{OC} = -\hat{\mathbf{i}} + \hat{\mathbf{i}}$$

**26.** 
$$\frac{3\hat{\mathbf{i}} - \hat{\mathbf{j}} - 3\hat{\mathbf{k}} + \hat{\mathbf{j}} + 3\hat{\mathbf{j}} - \hat{\mathbf{k}}}{2} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$

**27.** 
$$\frac{\mathbf{a} + \mathbf{b}}{2} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \frac{5}{2}\hat{\mathbf{k}}$$

**28.** It is given that **b** is collinear with the vector **a**.

$$\mathbf{b} = \lambda \mathbf{a} \qquad \dots(\mathbf{i})$$

$$= 2\sqrt{2}\lambda \hat{\mathbf{i}} - \lambda \hat{\mathbf{j}} + 4\lambda \hat{\mathbf{k}}$$

Also, 
$$| \mathbf{b} | = 10$$

$$\Rightarrow \sqrt{(2\sqrt{2}\lambda)^2 + (-\lambda)^2 + (4\lambda)^2} = 10$$

$$\Rightarrow 25\lambda^2 = 100$$

$$\Rightarrow \lambda = \pm 2 \qquad \dots \text{(ii)}$$

From Eqs. (i) and (ii), we have

$$\mathbf{b} = \pm 2\mathbf{a} \implies 2\mathbf{a} + \mathbf{b} = 0$$

**29.** Condition for collinearity,  $\mathbf{b} = \lambda \mathbf{a}$ 

$$\Rightarrow \qquad (-2\hat{\mathbf{i}} + m\hat{\mathbf{j}}) = \lambda (\hat{\mathbf{i}} - \hat{\mathbf{j}})$$

Comparison of coefficient, we get

$$\Rightarrow$$
  $\lambda = -2 \text{ and } -\lambda = m$ 

So, 
$$m=2$$

**30.** If given points be A, B and C, then AB = k(BC) or

$$2\hat{\mathbf{i}} - 8\hat{\mathbf{j}} = k[(a-12)\hat{\mathbf{i}} + 16\hat{\mathbf{j}}]$$

$$\Rightarrow$$
  $k = -\frac{1}{2}$ 

Also, 
$$2 = k (a - 12)$$

$$\Rightarrow$$
  $a = 8$ 

**31.** 
$$\begin{vmatrix} 1 & 2 & 3 \\ \lambda & 4 & 7 \\ -3 & -2 & -5 \end{vmatrix} = 0$$

$$\Rightarrow$$
  $\lambda = 3$ 

**32.**  $(\mathbf{a} - \mathbf{b}) - (\mathbf{a} + \mathbf{b}) = [(\mathbf{a} + k\mathbf{b}) - (\mathbf{a} - \mathbf{b})]$ 

$$\Rightarrow$$
  $-2\mathbf{b} = (k+1)\mathbf{b}$ 

Hence,  $k \in R$ 

**33.**  $AB = -\hat{i} - 4\hat{j}, CD = -2\hat{i} + (\lambda - 2)\hat{j}$ 

So, 
$$\frac{-1}{-2} = \frac{-4}{\lambda - 2} \Rightarrow \lambda - 2 = -8$$

$$\Rightarrow \lambda = -6$$

**34.** Obviously,  $\frac{3}{6} = \frac{2}{-4x} = -\frac{1}{y}$ 

$$\Rightarrow$$
  $x = -1$  and  $y = -2$ 

- **35.** If **a** and **b** are two non-zero, non-collinear vectors and x and y are two scalars such that  $x\mathbf{a} + y\mathbf{b} = 0$  then x = 0 and y = 0 because one will be a scalar multiple of the other and hence collinear which is a contradiction.
- **36.** Four or more than four non-zero vectors are always linearly dependent.
- **37.** These are coplanar because  $1(\mathbf{a}) + 1(\mathbf{b}) = \mathbf{a} + \mathbf{b}$
- **38.** Comparing the coefficients of  $\hat{i}$ ,  $\hat{j}$  and  $\hat{k}$ , and the corresponding equations are

$$x - (\lambda + 3)y + 5z = 0$$
 ... (ii)

$$3x + y - \lambda z = 0 \qquad \dots \text{(iii)}$$

These Eqs. (i), (ii) and (iii) have a non-trivial solution, if

$$\begin{vmatrix} (1-\lambda) & 3 & -4 \\ 1 & -(\lambda+3) & 5 \\ 3 & 1 & -\lambda \end{vmatrix} = 0 \Rightarrow \lambda = 0, -1$$

**39.** The vectors are linearly dependent

$$\Rightarrow \qquad \begin{vmatrix} p+1 & -3 & p \\ p & p+1 & -3 \end{vmatrix} = 0$$

$$\Rightarrow (2p-2)\begin{vmatrix} 1 & -3 & p \\ 1 & p+1 & -3 \\ 1 & p & p+1 \end{vmatrix} = 0$$

$$\Rightarrow 2(p-1)\begin{vmatrix} 1 & -3 & p \\ 0 & p+4 & -3-p \\ 0 & p+3 & 1 \end{vmatrix} = 0$$

$$\Rightarrow$$
 2(p-1)(p+4+(p+3)<sup>2</sup>) = 0

$$\Rightarrow$$
  $(p-1)(p^2 + 7p + 13) = 0$ 

Roots of  $p^2 + 7p + 13 = 0$  are (imaginary)

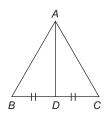

$$p=1$$

Only integral value of p is 1.

**40.** PV of AD =  $\frac{(3+5)\hat{\mathbf{i}} + (0-2)\hat{\mathbf{j}} + (4+4)\hat{\mathbf{k}}}{2}$ 

$$=4\hat{\mathbf{i}}-\hat{\mathbf{j}}+4\hat{\mathbf{k}}$$

$$|\mathbf{AD}| = \sqrt{16 + 16 + 1} = \sqrt{33}$$

41. v = b + c

$$\mathbf{w} = \mathbf{b} + \mathbf{a}$$

We have,  $\mathbf{x} = \mathbf{v} + \mathbf{w} = \mathbf{a} + 2\mathbf{b} + \mathbf{c}$ 

- **42.** Note that a + b = c
- **43.** Here is the only vector  $4(\sqrt{2}\hat{\mathbf{i}} + \hat{\mathbf{j}} \pm \hat{\mathbf{k}})$ , whose length is 8.
- **44.**  $3\mathbf{a} + 4\mathbf{b} + 5\mathbf{c} = 0$

Hence, **a**, **b** and **c** are coplanar.

No other conclusion can be derived from it.

**45.** A, B, C, D and E are five coplanar points.

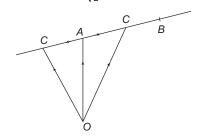

$$\mathbf{DA} + \mathbf{DB} + \mathbf{AE} + \mathbf{BE} + \mathbf{CE}$$
$$= (\mathbf{DA} + \mathbf{AE}) + (\mathbf{DB} + \mathbf{BE}) + (\mathbf{DC} + \mathbf{CE})$$
$$= \mathbf{DE} + \mathbf{DE} + \mathbf{DE} = 3\mathbf{DE}$$

**46.**  $\sqrt{3} \tan \theta + 1 = 0$  and  $\sqrt{3} \sec \theta - 2 = 0$ 

$$\Rightarrow \qquad \theta = \frac{11}{6}$$

$$\Rightarrow \qquad \theta = 2n\pi + \frac{11\pi}{6}, n \in \mathbb{Z}$$

- **47.**  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  are unit vectors along *Y* and *Z*-axes, then unit vector bisecting **OY** and **OZ** is  $\frac{\hat{\mathbf{j}} + \hat{\mathbf{k}}}{\sqrt{2}}$ .
- 48.

We have,  $A(\hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}})$  and  $B(\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + \hat{\mathbf{k}})$ 

On line AB points C and C' are at distance 1 unit from A.

OC = OA + AC, where AC is unit vector in direction of AB

$$\therefore \qquad \qquad \mathbf{OC} = \mathbf{OA} + \frac{\mathbf{AB}}{|\mathbf{AB}|}$$

Similarly, 
$$OC' = OA - \frac{AB}{|AB|}$$

$$49. AD = OD - OA$$

$$=\frac{\mathbf{b}+\mathbf{c}}{2}-\mathbf{a}=\frac{\mathbf{b}+\mathbf{c}-2\mathbf{a}}{2}$$

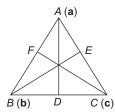

[where, *O* is the origin for reference]

Similarly, 
$$\mathbf{BE} = \mathbf{OE} - \mathbf{OB} = \frac{\mathbf{c} + \mathbf{a}}{2} - \mathbf{b}$$

$$=\frac{\mathbf{c}+\mathbf{a}-2\mathbf{l}}{2}$$

and

$$\mathbf{CF} = \frac{\mathbf{a} + \mathbf{b} - 2\mathbf{b}}{2}$$

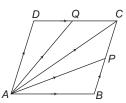

Now, 
$$\mathbf{AD} + \mathbf{BE} + \mathbf{CF} = \frac{\mathbf{b} + \mathbf{c} - 2\mathbf{a}}{2} + \frac{\mathbf{c} + \mathbf{a} - 2\mathbf{b}}{2} + \frac{\mathbf{a} + \mathbf{b} - 2\mathbf{c}}{2} = \mathbf{0}$$

$$+\frac{\mathbf{c}+\mathbf{a}-2\mathbf{b}}{2}+\frac{\mathbf{a}+\mathbf{b}-2\mathbf{c}}{2}=\mathbf{0}$$

**50.** 
$$AP = AB + BP = AB + \frac{1}{2}BC = AB + \frac{1}{2}AD$$

$$\mathbf{AQ} = \mathbf{AD} + \mathbf{DQ} = \mathbf{AD} + \frac{1}{2}\mathbf{DC} = \mathbf{AD} + \frac{1}{2}\mathbf{AB}$$
 ... (ii)

By Eqs. (i) and (ii), we get

$$AP + AQ = \frac{3}{2}(AB + AD)$$
$$= \frac{3}{2}(AB + BC) = \frac{3}{2}AC$$

**51.** Let 
$$A \equiv (1, 1, -1)$$
,  $B \equiv (2, 3, 0)$ ,  $C \equiv (3, 5, -2)$  and  $D \equiv (0, -1, 1)$ .

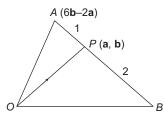

So, 
$$\mathbf{AB} = (1, 2, 1), \mathbf{BC} = (1, 2, -2), \mathbf{CD} = (-3, -6, 3)$$

and **DA** = 
$$(1, 2, -2)$$
.

Clearly, **BC** || **DA** but AB in not parallel to CD.

So, it is a trapezium.

**52.** 
$$\mathbf{OP} = \frac{1(\mathbf{OB}) + 2(6\mathbf{b} - 2\mathbf{a})}{1 + 2}$$

$$\Rightarrow 3(\mathbf{a} - \mathbf{b}) = \mathbf{OB} + 12\mathbf{b} - 4\mathbf{a}$$
$$\Rightarrow \mathbf{OB} = 7\mathbf{a} - 15\mathbf{b}$$

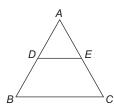

**53.** Let the *B* divide *AC* in ratio 
$$\lambda$$

$$5\hat{\mathbf{i}} - 2\hat{\mathbf{k}} = \frac{\lambda(11\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 7\hat{\mathbf{k}}) + \hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 8\hat{\mathbf{k}}}{\lambda + 1}$$

$$\Rightarrow 3\lambda - 2 = 0$$

$$\Rightarrow$$
  $\lambda = \frac{2}{3}$ , i.e. ratio = 2 : 3

## **54.** We know by fundamental theorem of proportionality that, $\mathbf{DE} = \frac{1}{2}\mathbf{BC}$

In triangle, 
$$BC = b - a$$

Hence, 
$$\mathbf{DE} = \frac{1}{2}(\mathbf{b} - \mathbf{a})$$

**55.** Since, 
$$AB + BD = AD$$

$$\mathbf{BD} = \mathbf{AD} - \mathbf{AB}$$

$$= (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}) - (2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}})$$

$$= -\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 8\hat{\mathbf{k}}$$

Hence, unit vector in the direction of **BD** is

$$\frac{-\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 8\hat{\mathbf{k}}}{|-\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 8\hat{\mathbf{k}}|} = \frac{-\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 8\hat{\mathbf{k}}}{\sqrt{69}}$$

## **56.** Position vectors of vertices A, B and C of the $\triangle ABC = \mathbf{a}, \mathbf{b}$ and c. We know that, position vector of centroid of the triangle,

$$G = \frac{\mathbf{a} + \mathbf{b} + \mathbf{c}}{3}.$$

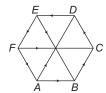

Therefore 
$$GA + GB + GG$$

Therefore, 
$$\mathbf{GA} + \mathbf{GB} + \mathbf{GC}$$

$$= \left(\mathbf{a} - \frac{\mathbf{a} + \mathbf{b} + \mathbf{c}}{3}\right) + \left(\mathbf{b} - \frac{\mathbf{a} + \mathbf{b} + \mathbf{c}}{3}\right) + \left(\mathbf{c} - \frac{\mathbf{a} + \mathbf{b} + \mathbf{c}}{3}\right)$$

$$= \frac{1}{3}(2\mathbf{a} - \mathbf{b} - \mathbf{c} + 2\mathbf{b} - \mathbf{a} - \mathbf{c} + 2\mathbf{c} - \mathbf{a} - \mathbf{b}) = 0$$

## **57.** A regular hexagon *ABCDEF*.

We know from the hexagon that AD is parallel to BC or AD = 2BC is parallel to FA or EB = 2FA and FC is parallel to  $\mathbf{AB}$  or  $\mathbf{FC} = 2\mathbf{AB}$ .

Thus, 
$$AD + EB + FC = 2BC + 2FA + 2AB$$
  
=  $2(FA + AB + BC) = 2(FC) = 2(2AB) = 4AB$ 

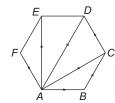

58. 
$$AE + ED + DC + AB$$

$$= AD + DC + AB = AC + AB$$

Obviously, if **BC** is added to this system, then it will be

$$AC + AB + BC = AC + AC = 2AC$$
.

**59.** By triangle law, 
$$AB = AD - BD$$
,  $AC = AD - CD$ 

Therefore,

$$\mathbf{AB} + \mathbf{AC} + \mathbf{AD} + \mathbf{AE} + \mathbf{AF}$$
$$= 3\mathbf{AD} + (\mathbf{AE} - \mathbf{BD}) + (\mathbf{AF} - \mathbf{CD}) = 3\mathbf{AD}$$
Hence,  $\lambda = 3$  (:  $\mathbf{AE} = \mathbf{BD}, \mathbf{AF} = \mathbf{CD}$ )

**60.** 
$$|a|+|b|+|c|=\sqrt{a^2+b^2+c^2}$$

$$\Leftrightarrow$$
 2 |  $ab$  | + 2 |  $bc$  | + 2 |  $ca$  | = 0

 $\Leftrightarrow ab = bc = ca = 0 \Leftrightarrow \text{any two of } a, b \text{ and } c \text{ are zero}$ 

**61.** Since, **a** and **b** are non-collinear, so  $\mathbf{a} + \mathbf{b}$  and  $\mathbf{a} - \mathbf{b}$  will also be non-collinear.

Hence,  $\mathbf{a} + \mathbf{b}$  and  $\mathbf{a} - \mathbf{b}$  are linearly independent vectors.

**62.** 
$$|a + b| < |a - b|$$

$$\Rightarrow \frac{\pi}{2} < \theta < \frac{3\pi}{2}$$

**63.** 
$$R = \sqrt{4 + 100 + 121} = 15$$

**64.** We must have 
$$\lambda(\hat{i} - 3\hat{j} + 5\hat{k}) = a + \frac{2\hat{k} + 2\hat{j} - \hat{i}}{3}$$

Therefore, 
$$3\mathbf{a} = 3\lambda(\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 5\hat{\mathbf{k}}) - (2\hat{\mathbf{k}} + 2\hat{\mathbf{j}} - \hat{\mathbf{i}})$$
  
 $= \hat{\mathbf{i}}(3\lambda + 1) - \hat{\mathbf{j}}(2 + 9\lambda) + \hat{\mathbf{k}}(15\lambda - 2)$   
or  $3|\mathbf{a}| = \sqrt{(3\lambda + 1)^2 + (2 + 9\lambda)^2 + (15\lambda - 2)^2}$ 

or 
$$9 = (3\lambda + 1)^2 + (2 + 9\lambda)^2 + (15\lambda - 2)^2$$

or 
$$315\lambda^2 - 18\lambda = 0 \Rightarrow \lambda = 0, \frac{2}{35}$$

If  $\lambda = 0$ ,  $\mathbf{a} = \hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$  (not acceptable)

For 
$$\lambda = \frac{2}{35}$$
,  $\mathbf{a} = \frac{41}{105}\hat{\mathbf{i}} - \frac{88}{105}\hat{\mathbf{j}} - \frac{40}{105}\hat{\mathbf{k}}$ 

**65.** 
$$\mathbf{b} = \cos 120^{\circ} \hat{\mathbf{i}} + \sin 120^{\circ} \hat{\mathbf{j}}$$

or 
$$\mathbf{b} = -\frac{1}{2}\hat{\mathbf{i}} + \frac{\sqrt{3}}{2}\hat{\mathbf{j}}$$

Therefore,  $\mathbf{a} + \mathbf{b} = \hat{\mathbf{i}} - \frac{1}{2}\hat{\mathbf{i}} + \frac{\sqrt{3}}{2}\hat{\mathbf{j}} = \frac{1}{2}\hat{\mathbf{i}} + \frac{\sqrt{3}}{2}\hat{\mathbf{j}}$ 

**66.**

and  $-3x - 6y = 12$   
 $\therefore \qquad x = 2, y = -3$   
 $\therefore \qquad \alpha = 2\mathbf{a} - 3\mathbf{b}$ 

**67.** Let the incentre be at the origin and be  $A(\mathbf{p}), B(\mathbf{q})$  and  $C(\mathbf{r})$ . Then,

$$IA = p, IB = q \text{ and } IC = r$$

Incentre *I* is 
$$\frac{ap + bq + cr}{a + b + c}$$
, where  $p = BC$ ,  $q = AC$  and  $r = AB$ 

Incentre is at the origin. Therefore,

$$\frac{a\mathbf{p} + b\mathbf{q} + c\mathbf{r}}{a + b + c} = \mathbf{0},$$
$$a\mathbf{b} + b\mathbf{q} + c\mathbf{r} = \mathbf{0}$$

 $a\mathbf{IA} + b\mathbf{IB} + c\mathbf{IC} = \mathbf{0}$ **68.** Since  $\mathbf{x}$ ,  $\mathbf{y}$  and  $\mathbf{x} \times \mathbf{y}$  are linearly independent, we have

$$20a - 15b = 15b - 12c = 12c - 20a = 0$$

$$\Rightarrow \frac{a}{3} = \frac{b}{4} = \frac{c}{5} \Rightarrow c^2 = a^2 + b^2$$

Hence,  $\triangle ABC$  is right angled.

**69.** As  $\mathbf{x}$ ,  $\mathbf{v}$  and  $\mathbf{x} \times \mathbf{v}$  are non-collinear vectors, vectors are linearly independent.

Hence,

or

$$a - b = 0 = b - c = c - a$$
  
or  $a = b = c$ 

Therefore, the triangle is equilateral.

$$k: 1 \text{ is } \frac{(5\hat{\mathbf{j}})k + (5\hat{\mathbf{i}})1}{k+1}$$

$$\therefore \qquad \mathbf{b} = \frac{5\hat{\mathbf{i}} + 5k\hat{\mathbf{j}}}{k+1}$$
Also
$$|\mathbf{b}| \le \sqrt{37}$$

$$\Rightarrow \frac{1}{k+1}\sqrt{25+25k^2} \le \sqrt{37}$$

 or  $(6k + 1)(k + 6) \ge 0$ 

$$k \in (-\infty, -6) \cup \left[ -\frac{1}{6}, \infty \right]$$

- **72.** Let the bisector of  $\angle A$  meets BC at D, then AD divides BC in the ratio AB : AC.
  - $\therefore$  Position vectors of D

$$= \frac{|\mathbf{A}\mathbf{B}|(2\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 7\hat{\mathbf{k}}) + |\mathbf{A}\mathbf{C}|(2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}})}{|\mathbf{A}\mathbf{B}| + |\mathbf{A}\mathbf{C}|}$$

Here, 
$$|\mathbf{A}\mathbf{B}| = |-2\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 4\hat{\mathbf{k}}| = 6$$

and 
$$|\mathbf{AC}| = |-2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - \hat{\mathbf{k}}| = 3$$
  
∴ Position vector of  $D$ 

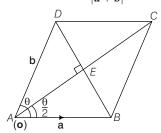

$$= \frac{6(2\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 7\hat{\mathbf{k}}) + 3(2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}})}{6 + 3}$$

$$= \frac{18\hat{\mathbf{i}} + 39\hat{\mathbf{j}} + 54\hat{\mathbf{k}}}{9}$$

$$= \frac{1}{3}(6\hat{\mathbf{i}} + 13\hat{\mathbf{j}} + 18\hat{\mathbf{k}})$$

**73.** Vector in the direction of angular bisector of **a** and **b** is  $\frac{\mathbf{a} + \mathbf{b}}{2}$ .

Unit vector in this direction is  $\frac{a+b}{|a+b|}$ 

From the figure, position vector of *E* is  $\frac{\mathbf{a} + \mathbf{b}}{2}$ .

Now in triangle AEB,  $AE = AB \cos \frac{\theta}{2}$ 

$$\Rightarrow \qquad \left| \frac{\mathbf{a} + \mathbf{b}}{2} \right| = \cos \frac{\theta}{2}$$

Hence, unit vector along the bisector is  $\frac{a+b}{2\cos{(\theta/2)}}$ 

74. 
$$\mathbf{a} - \mathbf{b} = 2(\mathbf{d} - \mathbf{c})$$

$$\therefore \frac{\mathbf{a} + 2\mathbf{c}}{2 + 1} = \frac{\mathbf{b} + 2\mathbf{d}}{2 + 1}$$

Hence, *AC* and *BD* trisect each other as LHS is the position vector of a point trisecting *A* an *C*, and RHS that of *B* and *D*.

**75.** Again, it is given that the point *P*, *Q* and *R* are collinear.

$$\Rightarrow \qquad \mathbf{PQ} = \lambda \mathbf{QR}$$

$$\Rightarrow \qquad 15t(4\hat{\mathbf{j}} - 3\hat{\mathbf{i}}) = \lambda [(1 - t)(\hat{\mathbf{i}} + \hat{\mathbf{j}}) - 60t\hat{\mathbf{j}}]$$

$$\Rightarrow \qquad = \lambda [(1 - t)\hat{\mathbf{i}} + (1 - 61t)\hat{\mathbf{j}}]$$

$$\Rightarrow \qquad \frac{45t}{t - 1} = \frac{60t}{1 - 61t}$$

$$\Rightarrow \qquad \frac{3t}{t - 1} = \frac{4t}{1 - 61t}$$

$$\Rightarrow \qquad 3(1 - 61t) = 4(t - 1)$$

$$\Rightarrow \qquad 3 - 183t = 4t - 4 \Rightarrow 187t = 7$$

$$\therefore \qquad t = \frac{7}{187}$$

**76.** We have,  $a + b + c = \alpha d$ 

and 
$$\mathbf{b} + \mathbf{c} + \mathbf{d} = \beta \mathbf{a}$$
  
 $\therefore$   $\mathbf{a} + \mathbf{b} + \mathbf{c} + \mathbf{d} = (\alpha + 1)\mathbf{d}$   
and  $\mathbf{a} + \mathbf{b} + \mathbf{c} + \mathbf{d} = (\beta + 1)\mathbf{a}$   
 $\Rightarrow$   $(\alpha + 1)\mathbf{d} = (\beta + 1)\mathbf{a}$   
If  $\alpha \neq -1$ , then  $(\alpha + 1)\mathbf{d} = (\beta + 1)\mathbf{a}$ 

$$\Rightarrow \qquad \mathbf{d} = \frac{\beta+1}{\alpha+1} \mathbf{a}$$

$$\Rightarrow \qquad \mathbf{a} + \mathbf{b} + \mathbf{c} = \alpha \mathbf{d}$$

$$\Rightarrow \qquad \mathbf{a} + \mathbf{b} + \mathbf{c} = \alpha \left(\frac{\beta+1}{\alpha+1}\right) \mathbf{a}$$

$$\Rightarrow \qquad \left[1 - \frac{\alpha(\beta+1)}{\alpha+1}\right] \mathbf{a} + \mathbf{b} + \mathbf{c} = 0$$

 $\boldsymbol{a},\boldsymbol{b}$  and  $\boldsymbol{c}$  are coplanar which is contradiction to the given condition.

$$\therefore \qquad \alpha = -1$$
 and so  $\mathbf{a} + \mathbf{b} + \mathbf{c} + \mathbf{d} = 0$ 

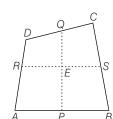

**77.** Since  $|\mathbf{OP}| = |\mathbf{OQ}| = \sqrt{14}$ ,  $\triangle OPQ$  is an isosceles.

Hence, the internal bisector *OM* is perpendicular to *PQ* and *M* is the mid-point of *P* and *Q*. Therefore,

$$\mathbf{OM} = \frac{1}{2}(\mathbf{OP} + \mathbf{OQ}) = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$

78.

Let 
$$OA = a, OB = b, OC = c$$
  
and  $OD = d$   
Therefore,  $OA + OB + OC + OD$   
 $= a + b + c + d$ 

- P, the mid-point of **AB**, is  $\frac{\mathbf{a} + \mathbf{b}}{2}$ .
- Q, the mid-point of **CD**, is  $\frac{\mathbf{c} + \mathbf{d}}{2}$ .

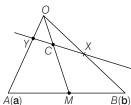

Therefore, the mid-point of PQ is  $\frac{a+b+c+d}{4}$ .

Similarly, the mid-point of RS is  $\; \frac{a+b+c+d}{4} \;$ 

i.e. 
$$OE = \frac{a + b + c + d}{4}$$

$$OQ = \frac{1}{2}\mathbf{b}, \mathbf{OR} = \frac{1}{3}\mathbf{c}.$$

Since P, Q, R and S are coplanar, then

$$\mathbf{PS} = \alpha \mathbf{PQ} + \beta \mathbf{PR}$$

(PS can be written as a linear combination of PQ and PR)

$$= \alpha(\mathbf{OQ} - \mathbf{OP}) + \beta(\mathbf{OR} - \mathbf{OP})$$

i.e. 
$$\mathbf{OS} - \mathbf{OP} = -(\alpha + \beta)\frac{\mathbf{a}}{3} + \frac{\alpha}{2}\mathbf{b} + \frac{\beta}{3}\mathbf{c}$$

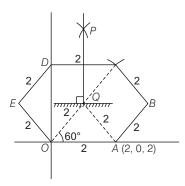

$$\Rightarrow \qquad \mathbf{OS} = (1 - \alpha - \beta)\frac{\mathbf{a}}{3} + \frac{\alpha}{2}\mathbf{b} + \frac{\beta}{3}\mathbf{c} \qquad \dots (i)$$

$$\Rightarrow$$
  $2\lambda = 1 + 3\lambda \text{ or } \lambda = -1$ 

82.

Here, coordinate of Q are  $(2\cos 60^{\circ}, 2\sin 60^{\circ})$ 

$$\Rightarrow Q(1, \sqrt{3}, 0)$$

$$\therefore \qquad P(1,\sqrt{3},z)$$

$$OP = 3$$

$$\therefore \qquad P(1,\sqrt{3},\sqrt{5}) \Rightarrow \mathbf{OP} = \hat{\mathbf{i}} + \sqrt{3}\hat{\mathbf{j}} + \sqrt{5}\hat{\mathbf{k}}$$

Now, 
$$\mathbf{AP} = \mathbf{OP} - \mathbf{OA} = \hat{\mathbf{i}} + \sqrt{3}\hat{\mathbf{j}} + \sqrt{5}\hat{\mathbf{k}} - 2\hat{\mathbf{i}}$$

$$= -\hat{\mathbf{i}} + \sqrt{3}\,\hat{\mathbf{j}} + \sqrt{5}\,\hat{\mathbf{k}}$$

**83.** 
$$\mathbf{a} = [\pm(\hat{\mathbf{i}} - \hat{\mathbf{j}}) \pm (\hat{\mathbf{j}} + \hat{\mathbf{k}})]$$

$$\mathbf{R} = \mathbf{F}_1 + \mathbf{F}_2 + \mathbf{F}_3 = (p+1)\hat{\mathbf{i}} + 4\hat{\mathbf{j}}$$

Given, 
$$|\mathbf{R}| = 5$$
. Therefore,  $(p+1)^2 + 16 = 25$ 

or 
$$p+1=\pm 3$$

**85.** We have, 
$$AB = -\hat{\mathbf{i}} - \hat{\mathbf{j}} - 4\hat{\mathbf{k}}, BC = -3\hat{\mathbf{i}} + 3\hat{\mathbf{j}}$$
  
and  $CA = 4\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}.$ 

Therefore, 
$$|\mathbf{AB}| = |\mathbf{BC}| = 3\sqrt{2}$$
 and  $|\mathbf{CA}| = 6$ 

 $|AB|^2 + |BC|^2 = |AC|^2$ Clearly,

Hence, the triangle is right angled isosceles triangle.

**86.** Let  $\mathbf{a} = 2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$  and  $\mathbf{b} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$ .

Then, the diagonals of the parallelogram are

and

$$q = b - a$$

$$\mathbf{p} = 3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}}, \mathbf{q} = -\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 8\hat{\mathbf{k}}$$

So, unit vectors along the diagonals are

$$= \frac{\lambda}{15} [2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}] = \frac{2\lambda}{15} [\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}]$$

**88.** Points  $A(\hat{\mathbf{i}} + \hat{\mathbf{j}})$ ,  $B(\hat{\mathbf{i}} - \hat{\mathbf{j}})$  and  $C(p\hat{\mathbf{i}} + q\hat{\mathbf{j}} + r\hat{\mathbf{k}})$  are collinear

Now, 
$$\mathbf{AB} = -2\hat{\mathbf{j}}$$

$$\mathbf{BC} = (p-1)\hat{\mathbf{i}} + (q+1)\hat{\mathbf{j}} + r\hat{\mathbf{k}}$$

Vectors AB and BC must be collinear

  $p = 1, r = 0 \text{ and } q \neq -1$ 

$$p = 1, r = 0 \text{ and } q \neq -1$$

**89.** For coplanar vectors,

 or  $\lambda = 0, \frac{1}{2}$ 

**90.** In 
$$\triangle ABC$$

or 
$$AB + BC + CA = 0$$

OA + AB = OB is the triangle law of addition.

Hence, Statement 1 is true and Statement 2 is is false.

**91.**

$$3(\mathbf{b} - \mathbf{a}) = 5(\mathbf{c} - \mathbf{a})$$

Hence, AB and AC must be parallel since there is a common point A. The points A, B and C must be collinear.

Solutions (Q.Nos. 93-94)

Let the position vectors of A, B, C and D be  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$  and  $\mathbf{d}$ , respectively. Then,

$$\Rightarrow 3\mathbf{d} = (\mathbf{b} - \mathbf{a}) = \mathbf{b} - 2(\mathbf{b} - \mathbf{c}) \qquad \text{[using Eq. (i)]}$$
$$= -\mathbf{b} + 2\mathbf{c} \qquad \dots \text{(ii)}$$

Let  $OX : XC = \lambda : 1$  and  $AX : XD = \mu : 1$ 

Now, *X* divides *OC* in the ratio  $\lambda$  : 1. Therefore,

PV of

*X* also divided *AD* in the ratio  $\mu$  : 1. Therefore,

PV of 
$$X = \frac{\mu \mathbf{d} + \mathbf{a}}{\mu + 1}$$
 ...(iv)

From Eqs. (iii) and (iv), we get

$$\frac{\lambda \mathbf{c}}{\lambda + 1} = \frac{\mu \mathbf{d} + \mathbf{a}}{\mu + 1}$$

$$r \qquad \left(\frac{\lambda}{\lambda+1}\right)\mathbf{c} = \left(\frac{\mu}{\mu+1}\right)\mathbf{d} + \left(\frac{1}{\mu+1}\right)\mathbf{a}$$

or

or 
$$\left(\frac{\lambda}{\lambda+1}\right)\mathbf{c} = \left(\frac{6-\mu}{3(\mu+1)}\right)\mathbf{b} + \left(\frac{2\mu}{3(\mu+1)} - \frac{2}{\mu+1}\right)\mathbf{c}$$

or 
$$\left(\frac{\lambda}{\lambda+1}\right)\mathbf{c} = \left(\frac{6-\mu}{3(\mu+1)}\right)\mathbf{b} + \left(\frac{2\mu-6}{3(\mu+1)}\right)\mathbf{c}$$

or 
$$\left(\frac{6-\mu}{3(\mu+1)}\right)\mathbf{b} + \left(\frac{2\mu-6}{3(\mu+1)} - \frac{\lambda}{\lambda+1}\right)\mathbf{c} = 0$$

$$\frac{6-\mu}{3(\mu+1)}=0$$

$$\frac{6-\mu}{3(\mu+1)}=0$$
 
$$\frac{2\mu-6}{3(\mu+1)}-\frac{\lambda}{\lambda+1}=0$$

(as b and c are non-collinear)

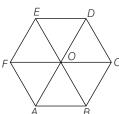

or 
$$\mu = 6, \lambda = \frac{2}{5}$$

Hence, OX : XC = 2 : 5 and  $AX / XD = \frac{\mu}{1} = \frac{6}{1}$

Consider the regular hexagon ABCDEF with centre at O (origin).

$$AD + EB + FC = 2AO + 2OB + 2OC$$

$$= 2(\mathbf{AO} + \mathbf{OB}) + 2\mathbf{OC}$$

$$= 2\mathbf{A}\mathbf{B} + 2\mathbf{A}\mathbf{B}$$

$$[:: AB = ED \text{ and } AF = CD]$$

$$= (AC + CD) + (AE + ED) + AD$$

$$= AD + AD + AD = 3AD = 6AO$$

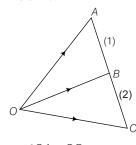

Solutions (Q.Nos. 97-99)

97. 
$$AB = OB - OA = 3a - b - 2c$$
  
 $AC = OC - OA = 9a - 3b - 6c = 3AB$

**99.** : 
$$2OA - 3OB + OC = 0$$

$$\Rightarrow OB = \frac{2OA + OC}{3}$$

**Solutions** (Q.Nos. 100-101)

**100.** Here,

$$\Rightarrow \quad \mathbf{c} = t\left(\frac{\hat{\mathbf{i}} - 7\hat{\mathbf{j}} + 2\hat{\mathbf{k}}}{9}\right)$$

Also, 
$$|\mathbf{c}| = 5\sqrt{6} \implies \frac{t}{9} \cdot \sqrt{1 + 49 + 4} = 5\sqrt{6}$$

$$\Rightarrow \qquad 2BD \cdot BE = (BD + BE) \cdot BC$$

**Solutions** (Q.Nos. 102-103)

**102.** 
$$r'(t) = -2\hat{\mathbf{i}} + 2t\hat{\mathbf{j}} + 4e^{2(t-1)}\hat{\mathbf{k}}$$

Since, 
$$r'(t)$$

so 
$$r(t) = \alpha r'(t)$$
  
  $1 - 2t = -2\alpha, t^2 = \alpha t, 2e^{2(t-1)}$ 

$$=4\alpha e^{2(t-1)},\alpha=\frac{1}{2}$$

The only value of t which satisfies all three equations is t = 1. So, r(1) is the required point (-1, 1, 2).

**103.** (2, 0, 5) corresponding to 
$$r(1)$$

Clearly the vector along the longer diagonal is

$$\mathbf{a} + \mathbf{b} = 3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

Hence, length of the longer diagonal is

$$|\mathbf{a} + \mathbf{b}| = |3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} + 2\hat{\mathbf{k}}| = 7$$

**107.** Vector  $\mathbf{a} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$ ,  $\mathbf{b} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}$ ,  $\mathbf{c} = \lambda\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$  are coplanar.

$$\Rightarrow \frac{\mathbf{AI} \cdot \mathbf{BI} \cdot \mathbf{CI}}{\mathbf{AA'} \cdot \mathbf{BB'} \cdot \mathbf{CC'}} = \frac{(b+c)(a+c)(a+b)}{(a+b+c)(a+b+c)(a+b+c)} \qquad \dots (i)$$

As we know  $AM \ge GM$ , we get

$$\frac{b+c}{a+b+c} + \frac{c+a}{a+b+c} + \frac{a+b}{a+b+c} \ge \left[ \frac{(a+b)(b+c)(c+a)}{(a+b+c)^3} \right]^{\frac{1}{3}}$$

$$\Rightarrow \frac{2(a+b+c)}{3(a+b+c)} \ge \frac{[(a+b)(b+c)(c+a)]^{1/3}}{a+b+c}$$

$$\Rightarrow \frac{(a+b)(b+c)(c+a)}{(a+b+c)} \le \frac{8}{27} \qquad \dots (ii)$$

From Eqs. (i) and (ii), we get

$$\frac{AI \cdot BI \cdot CI}{AA' \cdot BB' \cdot CC'} \le \frac{8}{27}$$

**117.** Let the position vector of O' with reference to O as the origin be  $\alpha$ .

Then, 
$$\mathbf{OO'} = \alpha$$

Now,  $\mathbf{O}' P_i$  = Position vector

or  $P_i$  – Position vector of  $O' = \mathbf{r}_i - \alpha$ 

$$i = 1, 2, ...., n$$

Let the position vectors of  $P_1$ ,  $P_2$ ,  $P_3$ ,.....,  $P_n$  with respect to O' as the origin be  $\mathbf{R}_1$ ,  $\mathbf{R}_2$ .....,  $\mathbf{R}_n$  respectively. Then,  $\mathbf{R}_i = \mathbf{O'}$ 

$$P_i = \mathbf{r}_i - \alpha, i = 1, 2, ...., n$$
 [using Eq. (i)]

Now,  $a_1$ **R**<sub>1</sub> +  $a_2$ **R**<sub>2</sub> + ..... +  $a_n$ **R**<sub>n</sub> = 0

$$\Rightarrow \sum_{i=1}^{n} a_{i} \mathbf{R}_{i} = 0 \Rightarrow \sum_{i=1}^{n} \mathbf{a}_{i} (\mathbf{r}_{i} - \alpha) = 0$$

$$\Rightarrow \sum_{i=1}^{n} a_{i} \mathbf{r}_{i} - \sum_{i=1}^{n} a_{i} \alpha = 0$$

$$\Rightarrow \qquad \qquad 0 - \alpha \left( \sum_{i=1}^{n} a_i \right) = 0 \qquad \qquad \left[ \because \sum_{i=1}^{n} a_i \mathbf{r}_i = 0 \text{ (given)} \right]$$

$$\Rightarrow \sum_{i=1}^{n} a_i = 0$$

Thus, 
$$\sum_{i=1}^{n} a_i \mathbf{R}_i = 0$$
 will hold good, if  $\sum_{i=1}^{n} a_i = 0$ .

**118.** Let *O* be the origin of reference.

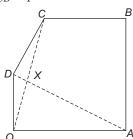

Then,

 $\Rightarrow$ 

Let the position vectors of A, B, C and D be  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$  and  $\mathbf{d}$ , respectively.

$$OA:CB=2:1$$

$$\Rightarrow \frac{OA}{CB} = \frac{2}{1} \Rightarrow OA + 2CB$$

$$\mathbf{OA} = 2\mathbf{CB}$$

$$\mathbf{a} = 2(\mathbf{b} - \mathbf{c})$$
 ...(i)

and 
$$OD: AB = 1:3$$

$$\Rightarrow \frac{OD}{AB} = \frac{1}{3} \Rightarrow 3OD = AB$$

$$\Rightarrow$$
 3OD = AB

$$\Rightarrow 3\mathbf{d} = (\mathbf{b} - \mathbf{a}) = \mathbf{b} - 2(\mathbf{b} - \mathbf{c})$$
 [using Eq. (i)]

$$\Rightarrow 3\mathbf{d} = -\mathbf{b} + 2\mathbf{c} \qquad \dots(ii)$$

Let  $OX : XC = \lambda : 1$  and  $AX : XD = \mu : 1$ 

Now, *X* divides *OC* in the ratio  $\lambda$  : 1. Therefore,

PV of 
$$X = \frac{\lambda c}{\lambda + 1}$$
 ...(iii)

*X* also divides *AD* in the ratio  $\mu$  : 1

PV of 
$$X = \frac{\mu \mathbf{d} + \mathbf{a}}{\mu + 1}$$

From Eqs. (iii) and (iv), we get

$$\frac{\lambda c}{\lambda + 1} = \frac{\mu \mathbf{d} + \mathbf{a}}{\mu + 1}$$

$$\Rightarrow \qquad \left(\frac{\lambda}{\lambda+1}\right)\mathbf{c} = \left(\frac{\mu}{\mu+1}\right)\mathbf{d} + \left(\frac{1}{\mu+1}\right)\mathbf{a}$$

[using Eqs. (i) and (iv)

$$\Rightarrow \qquad \left(\frac{\lambda}{\lambda+1}\right)\mathbf{c} = \left(\frac{2}{\mu+1} - \frac{\mu}{3(\mu+1)}\right)\mathbf{b}$$

$$+\left(\frac{2\mu}{3(\mu+1)}-\frac{2}{\mu+1}\right)\mathbf{c}$$

$$\Rightarrow \qquad \qquad \left(\frac{\lambda}{\lambda+1}\right)\mathbf{c} = \left(\frac{6-\mu}{3(\mu+1)}\right)\mathbf{b} + \left(\frac{2\mu-6}{3(\mu+1)}\right)\mathbf{c}$$

$$\Rightarrow \left(\frac{6-\mu}{3(\mu+1)}\right)\mathbf{b} + \left(\frac{2\mu-6}{3(\mu+1)} - \frac{\lambda}{\lambda+1}\right)\mathbf{c} = 0$$

$$\Rightarrow \frac{6-\mu}{3(\mu+1)} = 0 \text{ and } \frac{2\mu-6}{3(\mu+1)} - \frac{\lambda}{\lambda+1} = 0$$

(since, b and c are non-collinear

$$\Rightarrow$$
  $\mu = 6 \text{ and } \lambda = \frac{2}{5}$ 

Hence, OX: XC = 2:5

**119.** let l, m and n be scalars such that

$$l\mathbf{p} + m\mathbf{q} + n\mathbf{r} = 0$$

$$\Rightarrow \{l(\cos a)\mathbf{u} + (\cos b)\mathbf{v} + (\cos c)\mathbf{w}\} + m\{(\sin a)\mathbf{u}\}$$

$$+ (\sin b)\mathbf{v} + (\sin c)\mathbf{w}$$

$$+ n\{\sin(x+a)\mathbf{u} + \sin(x+b)\mathbf{v} + \sin(x+c)\mathbf{w}\} = 0$$

$$\Rightarrow \{l\cos a + m\sin a + n\sin(x+a)\}\mathbf{u} + \{l\sin b + m\sin(x+b)\}\mathbf{v} + \{l\cos c + m\sin c + n\sin(x+c)\}\mathbf{w} = 0$$

$$\Rightarrow l\cos a + m\sin a + n\sin(x + a) = 0 \qquad ...(i)$$

$$l\cos b + m\sin b + n\sin(x+b) = 0 \qquad ...(ii)$$

$$l\cos c + m\sin c + n\sin(x+c) = 0 \qquad ...(iii)$$

This is a homogeneous system of linear equations in l, m and n. The determinant of the coefficient matrix is

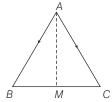

$$\Delta = \begin{vmatrix} \cos a & \sin a & \sin(x+a) \\ \cos b & \sin b & \sin(x+b) \\ \cos c & \sin c & \sin(x+c) \end{vmatrix} = \begin{vmatrix} \cos a & \sin a & 0 \\ \cos b & \sin b & 0 \\ \cos c & \sin c & 0 \end{vmatrix} = 0$$

(using 
$$C_3 \rightarrow C_3 - \sin x C_1 - \cos x C_2$$
)

 $\Rightarrow$  So, the above system of equations has non-trivial solutions also. This means that l, m and n may attain non-zero values also

Hence, the given system of vectors is a linearly dependent system of vectors.

**120.** We know that, the sum of three vectors of a triangle is zero.

$$\therefore \mathbf{AB} + \mathbf{BC} + \mathbf{CA} = 0$$

$$\Rightarrow \qquad BC = AC - AB \qquad [\because AC = -CA]$$

$$\Rightarrow \qquad \mathbf{AB} = \frac{\mathbf{AC} - \mathbf{AB}}{2} \qquad [\because M \text{ is a mid-point of } BC]$$

Also, 
$$AB + BM + MA = 0$$

[by properties of a triangle]

61

$$AB + \frac{AC - AB}{2} = AM \qquad [\because AM = -MA]$$

$$AM = \frac{AB + AC}{2}$$

$$= \frac{3\hat{\mathbf{i}} + 4\hat{\mathbf{k}} + 5\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}}{2}$$

$$= 4\hat{\mathbf{i}} - \hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$

$$|\mathbf{AM}| = \sqrt{4^2 + 1^2 + 4^2} = \sqrt{33}$$

**121.** As, 
$$\mathbf{a} + 3\mathbf{b}$$
 is collinear with  $\mathbf{c}$ .

$$\mathbf{a} + 3\mathbf{b} = \lambda \mathbf{c} \qquad \dots (i)$$

Also,  $\mathbf{b} + 2\mathbf{c}$  is collinear with  $\mathbf{a}$ .

$$\Rightarrow$$
  $\mathbf{b} + 2\mathbf{c} = \mu \mathbf{a}$  ...(ii)

From Eq. (ii), we get

$$\mathbf{a} + 3\mathbf{b} + 6\mathbf{c} = (\lambda + 6)\mathbf{c}$$
 ...(iii)

From Eq. (ii), we get

$$\mathbf{a} + 3\mathbf{b} + 6\mathbf{c} = (1 + 3\mu)\mathbf{a}$$
 ...(iv)

From Eqs. (iii) and (iv), we get

$$\therefore (\lambda + 6) \mathbf{c} = (1 + 3\mu) \mathbf{a}$$

Since, a is not collinear with c.

$$\lambda + 6 = 1 + 3\mu = 0$$

From Eq. (iv), we get

$$\mathbf{a} + 3\mathbf{b} + 6\mathbf{c} = 0$$

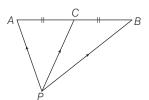

#### **122.** Since, a = 8b and c = -7b

So,  $\mathbf{a}$  is parallel to  $\mathbf{b}$  and  $\mathbf{c}$  is anti-parallel to  $\mathbf{b}$ .

 $\Rightarrow$  **a** and **c** are anti-parallel.

So, the angle between **a** and **c** is  $\pi$ .

**123.** Let *P* be the origin outside of *AB* and *C* is mid-point of *AB*, then

$$PC = \frac{PA + PB}{2} \implies 2PC = PA + PB$$

**124.** If 
$$a + 2b$$
 is collinear with **c**, then  $a + 2b = tc$  ...(i)

Also,  $\mathbf{b} + 3\mathbf{c}$  is collinear with  $\mathbf{a}$ , then

$$\mathbf{b} + 3\mathbf{c} = \lambda \mathbf{a}$$

$$\mathbf{b} = \lambda \mathbf{a} - 3\mathbf{c} \qquad \dots(ii)$$

From Eqs. (i) and (ii), we get

$$\mathbf{a} + 2(\lambda \mathbf{a} - 3\mathbf{c}) = t\mathbf{c}$$

$$\Rightarrow \qquad (\mathbf{a} - 6\mathbf{c}) = t\mathbf{c} - 2\lambda a$$

On comparing the coefficients of a and c, we get

$$1 = -2\lambda \implies \lambda = -\frac{1}{2}$$

and 
$$-6 = t \implies t = -6$$

From Eq. (i), we get

$$\mathbf{a} + 2\mathbf{b} = -6\mathbf{c}$$

$$\Rightarrow \qquad \mathbf{a} + 2\mathbf{b} + 6\mathbf{c} = 0$$

**125.** The three vectors  $(\mathbf{a} + 2\mathbf{b} + 3\mathbf{c})$ ,  $(\lambda \mathbf{b} + 4\mathbf{c})$  and  $(2\lambda - 1)\mathbf{c}$  are non-coplanar, if

$$\begin{vmatrix} 1 & 2 & 3 \\ 0 & \lambda & 4 \\ 0 & 0 & 2\lambda - 1 \end{vmatrix} \neq 0$$

$$\Rightarrow \qquad (2\lambda - 1)(\lambda) \neq 0$$

$$\Rightarrow \qquad \lambda \neq 0, \frac{1}{2}$$

So, these three vectors are non-coplanar for all except two values of  $\lambda$ .

**126.** Given that,  $\mathbf{OA} = 7\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 7\hat{\mathbf{k}}$ 

$$\mathbf{OB} = \hat{\mathbf{i}} - 6\,\hat{\mathbf{j}} + 10\,\hat{\mathbf{k}}$$

$$\mathbf{OC} = -\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$

$$\mathbf{OD} = 5\hat{\mathbf{i}} - \hat{\mathbf{j}} + 5\hat{\mathbf{k}}$$

OD = 
$$5\hat{\mathbf{i}} - \hat{\mathbf{j}} + 5\hat{\mathbf{k}}$$
  
Now,  $AB = \sqrt{(7-1)^2 + (-4+6)^2 + (7-10)^2}$   
 $= \sqrt{36+4+9}$   
 $= \sqrt{49} = 7$   
 $BC = \sqrt{(1+1)^2 + (-6+3)^2 + (10-4)^2}$   
 $= \sqrt{4+9+36}$   
 $= \sqrt{49} = 7$   
 $CD = \sqrt{(-1-5)^2 + (-3+1)^2 + (4-5)^2}$   
 $= \sqrt{36+4+1}$   
 $= \sqrt{41}$ 

and 
$$DA = \sqrt{(5-7)^2 + (-1+4)^2 + (5-7)^2}$$
$$= \sqrt{4+9+4}$$
$$= \sqrt{17}$$

Hence, option (d) is correct.

127. Since, 
$$\begin{vmatrix} a & a^2 & 1 + a^3 \\ b & b^2 & 1 + b^3 \\ c & c^2 & 1 + c^3 \end{vmatrix} = \begin{vmatrix} a & a^2 & 1 \\ b & b^2 & 1 \\ c & c^2 & 1 \end{vmatrix} + \begin{vmatrix} a & a^2 & a^3 \\ b & b^2 & b^3 \\ c & c^2 & c^3 \end{vmatrix} = 0$$

$$\Rightarrow \begin{vmatrix} a & a^2 & 1 \\ b & b^2 & 1 \\ c & c^2 & 1 \end{vmatrix} = abc \begin{vmatrix} a & a^2 & 1 \\ b & b^2 & 1 \\ c & c^2 & 1 \end{vmatrix} = 0$$

$$\Rightarrow (1 + abc) \begin{vmatrix} a & a^2 & 1 \\ b & b^2 & 1 \\ c & c^2 & 1 \end{vmatrix} = 0$$

$$\Rightarrow 1 + abc = 0$$

$$\Rightarrow abc = -1$$

**128.** Since, the vector  $\hat{\mathbf{i}} + x\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  is doubled in magnitude, then it becomes

$$4\hat{\mathbf{i}} + (4x - 2)\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

$$\therefore \qquad 2 | \hat{\mathbf{i}} + x\hat{\mathbf{j}} + 3\hat{\mathbf{k}} | = 4\hat{\mathbf{i}} + (4x - 2)\hat{\mathbf{j}} + 2\mathbf{k} |$$

$$\Rightarrow \qquad 2 \sqrt{1 + x^2 + 9} = \sqrt{16 + (4x - 2)^2 + 4}$$

$$\Rightarrow \qquad 40 + 4x^2 = 20 + (4x - 2)^2$$

$$\Rightarrow \qquad 3x^2 - 4x - 4 = 0$$

$$\Rightarrow \qquad (x - 2)(3x + 2) = 0$$

$$\Rightarrow \qquad x = 2, -\frac{2}{3}$$

## **Session 1**

## **Product of Two Vectors, Components of a Vector** Along and Perpendicular to Another Vector, **Application of Dot Product in Mechanics**

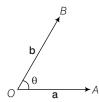

## **Product of Two Vectors**

Product of two vectors is processed by two methods. When the product of two vectors results in a scalar quantity, then it is called **scalar product**. It is also known as **dot product** because we denote it by putting a **dot** (.) between two vectors.

When the product of two vectors results in a vector quantity, then this product is called **vector product**. It is also known as **cross product** because we denote it by putting a **cross** (x) between two vectors.

## Scalar or Dot Product of Two Vectors

If **a** and **b** are two non-zero vectors and  $\theta$  be the angle between them, then their scalar product (or dot product) is denoted by  $\mathbf{a} \cdot \mathbf{b}$  and is defined as the scalar  $|\mathbf{a}| |\mathbf{b}| \cos \theta$ , where  $|\mathbf{a}|$  and  $|\mathbf{b}|$  are modulii of a and b respectively and  $0 \le \theta \le \pi$ .

#### Remarks

1.  $\mathbf{a} \cdot \mathbf{b} \in R$ 

2.  $a \cdot b \le |a| |b|$ 

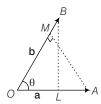

**3.**  $\mathbf{a} \cdot \mathbf{b} > 0 \Rightarrow$  Angle between  $\mathbf{a}$  and  $\mathbf{b}$  is acute.

**4.**  $\mathbf{a} \cdot \mathbf{b} < 0 \Rightarrow \text{Angle between } \mathbf{a} \text{ and } \mathbf{b} \text{ is obtuse.}$ 

**5.** The dot product of a zero and non-zero vector is a scalar zero.

## Geometrical interpretation of scalar product

Let a and b be two vectors represented by OA and OB respectively. Let  $\theta$  be the angle between **OA** and **OB**. Draw  $BL \perp OA$  and  $AM \perp OB$ .

From triangles *OBL* and *OAM*, we have  $OL = OB \cos \theta$ and  $OM = OA \cos \theta$ . Here, OL and OA are known as projection of **b** on **a** and **a** on **b** respectively.

Now, 
$$\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos \theta$$
  
=  $|\mathbf{a}| (OB \cos \theta) = |\mathbf{a}| (OL)$   
= (Magnitude of **a**) (Projection of **b** on **a**) ...(i)

Again, 
$$\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos \theta$$
  
=  $|\mathbf{b}| (|\mathbf{a}| \cos \theta) = |\mathbf{b}| (OA \cos \theta) = |\mathbf{b}| (OM)$   
 $\mathbf{a} \cdot \mathbf{b} = (Magnitude \text{ of } \mathbf{b})$ 

Thus, geometrically interpreted, the scalar product of two vectors is the product of modulus of either vector and the projection of the other in

(Projection of **a** on **b**) ...(ii)

its direction.

1. Projection of **a** on  $\mathbf{b} = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{b}|} = \mathbf{a} \cdot \mathbf{b}$ 2. Projection of **b** on  $\mathbf{a} = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|} = \mathbf{a} \cdot \mathbf{b}$ 

3. Angle between two vectors it a and b be two vectors inclined at an angle  $\theta$ , then  $\mathbf{a}$ ,  $\mathbf{b} = |\mathbf{a}| \cdot |\mathbf{b}| \cos \theta$ 

$$\Rightarrow \qquad \cos\theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| \cdot |\mathbf{b}|}$$

$$\Rightarrow \qquad \theta = \cos^{-1} \left( \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| \cdot |\mathbf{b}|} \right)$$

If 
$$\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$$
 and  $\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$ 

$$\theta = \cos^{-1} \left( \frac{a_1 b_1 + a_2 b_2 + a_3 b_3}{\sqrt{a_1^2 + a_2^2 + a_3^2} \sqrt{b_1^2 + b_2^2 + b_3^2}} \right)$$

## **Properties of Scalar Product**

- (i) **Commutativity** The scalar product of two vector is commutative i.e.,  $\mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{a}$ .
- (ii) Distributivity of scalar product over vector addition The scalar product of vectors is distributive over vector addition i.e.,
  - (a)  $\mathbf{a} \cdot (\mathbf{b} + \mathbf{c}) = \mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c}$  (Left distributivity)
  - (b)  $(\mathbf{b} + \mathbf{c}) \cdot \mathbf{a} = \mathbf{b} \cdot \mathbf{a} + \mathbf{c} \cdot \mathbf{a}$  (right distributivity)
- (iii) Let **a** and **b** be two non-zero vectors  $\mathbf{a} \cdot \mathbf{b} = 0 \Leftrightarrow \mathbf{a} \perp \mathbf{b}$ . As  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  are mutually perpendicular unit vectors along the coordinate axes, therefore
  - $\hat{\mathbf{i}} \cdot \hat{\mathbf{j}} = \hat{\mathbf{j}} \cdot \hat{\mathbf{i}} = 0, \ \hat{\mathbf{j}} \cdot \hat{\mathbf{k}} = \hat{\mathbf{k}} \cdot \hat{\mathbf{j}} = 0; \ \hat{\mathbf{k}} \cdot \hat{\mathbf{i}} = \hat{\mathbf{i}} \cdot \hat{\mathbf{k}} = 0$
- (iv) For any vector  $\mathbf{a}, \mathbf{a} \cdot \mathbf{a} = |\mathbf{a}|^2$ . As  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  are unit vectors along the coordinate axes, therefore  $\hat{\mathbf{i}} \cdot \hat{\mathbf{i}} = |\hat{\mathbf{i}}|^2 = 1$ ,  $\hat{\mathbf{j}} \cdot \hat{\mathbf{j}} = |\hat{\mathbf{j}}|^2 = 1$  and  $\hat{\mathbf{k}} \cdot \hat{\mathbf{k}} = |\hat{\mathbf{k}}|^2 = 1.$
- (v) If *m* is a scalar and **a** and **b** be any two vectors then  $(ma) \cdot \mathbf{b} = m(\mathbf{a} \cdot \mathbf{b}) = \mathbf{a} \cdot (m\mathbf{b}).$
- (vi) If *m* and *n* are scalars and **a** and **b** be two vectors, then  $(m\mathbf{a}) \cdot n\mathbf{b} = mn(\mathbf{a} \cdot \mathbf{b}) = (mn\mathbf{a}) \cdot \mathbf{b} = \mathbf{a} \cdot (mn\mathbf{b})$
- (vii) For any vectors **a** and **b**, we have
  - (a)  $\mathbf{a} \cdot (-\mathbf{b}) = -(\mathbf{a} \cdot \mathbf{b}) = (-\mathbf{a}) \cdot \mathbf{b}$
  - (b)  $(-\mathbf{a}) \cdot (-\mathbf{b}) = \mathbf{a} \cdot \mathbf{b}$
- (viii) For any two vectors **a** and **b**, we have
  - (a)  $|\mathbf{a} + \mathbf{b}|^2 = |\mathbf{a}|^2 + |\mathbf{b}|^2 + 2\mathbf{a} \cdot \mathbf{b}$
  - (b)  $|\mathbf{a} \mathbf{b}| = |\mathbf{a}|^2 + |\mathbf{b}|^2 2\mathbf{a} \cdot \mathbf{b}$
  - (c)  $(a + b) \cdot (a b) = |a|^2 |b|^2$
  - (d)  $|\mathbf{a} + \mathbf{b}| = |\mathbf{a}| + |\mathbf{b}| \implies \mathbf{a} ||\mathbf{b}|$
  - (e)  $|\mathbf{a} + \mathbf{b}|^2 = |\mathbf{a}|^2 + |\mathbf{b}|^2 \implies \mathbf{a} \perp \mathbf{b}$
  - (f)  $|\mathbf{a} + \mathbf{b}| = |\mathbf{a} \mathbf{b}| \Rightarrow \mathbf{a} \perp \mathbf{b}$

## Scalar Product in Terms of Components

If  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$  and  $\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$ , then  $\mathbf{a} \cdot \mathbf{b} = a_1 b_1 + a_2 b_2 + a_3 b_3.$ 

Thus, scalar product of two vectors is equal to the sum of the products of their corresponding components. In particular,  $\mathbf{a} \cdot \mathbf{a} = |\mathbf{a}|^2 = a_1^2 + a_2^2 + a_3^2$ .

- **Example 1.** If  $\theta$  is the angle between the vectors  $\mathbf{a} = 2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$  and  $\mathbf{b} = 6\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ , then
  - (a)  $\cos\theta = \frac{4}{21}$
- (b)  $\cos\theta = \frac{3}{10}$
- (c)  $\cos\theta = \frac{2}{10}$
- (d)  $\cos\theta = \frac{5}{21}$

**Sol.** (a) Angle between **a** and **b** is given by

$$\cos \theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| |\mathbf{b}|}$$

$$= \frac{(2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}) \cdot (6\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}})}{\sqrt{2^2 + 2^2 + (-1)^2} \cdot \sqrt{6^2 + (-3)^2 + 2^2}}$$

$$= \frac{12 - 6 - 2}{3 \cdot 7} = \frac{4}{21}$$

- **Example 2.**  $(\mathbf{a} \cdot \hat{\mathbf{i}}) \hat{\mathbf{i}} + (\mathbf{a} \cdot \hat{\mathbf{j}}) \hat{\mathbf{j}} + (\mathbf{a} \cdot \hat{\mathbf{k}}) \hat{\mathbf{k}}$  is equal to
  - (a) **a**

(b) 2a

(c) 3**a** 

(d) **0** 

**Sol.** (a) Let 
$$\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$$
  
 $\mathbf{a} \cdot \hat{\mathbf{i}} = (a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{i}} + a_3 \hat{\mathbf{k}})$ 

So, 
$$(\mathbf{a} \cdot \hat{\mathbf{i}})\hat{\mathbf{i}} + (\mathbf{a} \cdot \hat{\mathbf{j}})\hat{\mathbf{j}} + (\mathbf{a} \cdot \hat{\mathbf{k}})\hat{\mathbf{k}}$$
  
=  $a_1\hat{\mathbf{i}} + a_2\hat{\mathbf{j}} + a_3\hat{\mathbf{k}} = \mathbf{a}$

$$(\mathbf{a} + \lambda \mathbf{b}) \cdot (\mathbf{a} - \lambda \mathbf{b}) = 0$$

$$\Rightarrow |\mathbf{a}^2| - \lambda (\mathbf{a} \cdot \mathbf{b}) + \lambda (\mathbf{b} \cdot \mathbf{a}) - \lambda^2 |\mathbf{b}|^2 = 0$$

$$\Rightarrow |\mathbf{a}|^2 - \lambda^2 |\mathbf{b}|^2 = 0$$

$$= \frac{2 + 6 - 6}{\sqrt{14}} = \frac{2}{\sqrt{14}}$$

**| Example 5.** If  $\mathbf{a} = 5\hat{\mathbf{i}} - \hat{\mathbf{j}} + 7\hat{\mathbf{k}}$  and  $\mathbf{b} = \hat{\mathbf{i}} - \hat{\mathbf{j}} + \lambda\hat{\mathbf{k}}$ , then find  $\lambda$  such that  $\mathbf{a} + \mathbf{b}$  and  $\mathbf{a} - \mathbf{b}$  are orthogonal.

**Sol.** Clearly, 
$$\mathbf{a} + \mathbf{b} = (5\hat{\mathbf{i}} - \hat{\mathbf{j}} + 7\hat{\mathbf{k}}) + (\hat{\mathbf{i}} - \hat{\mathbf{j}} + \lambda\hat{\mathbf{k}})$$
$$= 6\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + (7 + \lambda)\hat{\mathbf{k}}$$

and 
$$\mathbf{a} - \mathbf{b} = (5\hat{\mathbf{i}} - \hat{\mathbf{j}} + 7\hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}} + \lambda\hat{\mathbf{k}})$$
  
=  $4\hat{\mathbf{i}} + (7 - \lambda)\hat{\mathbf{k}}$ 

Since,  $\mathbf{a} + \mathbf{b}$  and  $\mathbf{a} - \mathbf{b}$  are orthogonal

$$(\mathbf{a} + \mathbf{b}) \cdot (\mathbf{a} - \mathbf{b}) = 0$$

$$\Rightarrow [6\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + (7 + \lambda) \hat{\mathbf{k}}] (4\hat{\mathbf{i}} + (7 - \lambda) \hat{\mathbf{k}}) = 0$$

$$\Rightarrow 6 \times 4 - 2 \times 0 + (7 + \lambda) (7 - \lambda) = 0$$

$$\Rightarrow 24 + 49 - \lambda^{2} = 0$$

$$\Rightarrow \qquad \lambda^2 = 73$$

$$\Rightarrow \qquad \lambda = \pm \sqrt{73}$$

**Example 6.** If  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are unit vectors such that  $\mathbf{a} + \mathbf{b} + \mathbf{c} = 0$ , then find the value of  $\mathbf{a} \cdot \mathbf{b} + \mathbf{b} \cdot \mathbf{c} + \mathbf{c} \cdot \mathbf{a}$ .

**Sol.** Consider,  $\mathbf{a} + \mathbf{b} + \mathbf{c} = 0$ 

On squaring both sides, we get

$$(\mathbf{a} + \mathbf{b} + \mathbf{c})^{2} = 0^{2}$$

$$\Rightarrow (\mathbf{a} + \mathbf{b} + \mathbf{c}) \cdot (\mathbf{a} + \mathbf{b} + \mathbf{c}) = 0 \cdot 0$$

$$\Rightarrow |\mathbf{a}|^{2} + |\mathbf{b}|^{2} + |\mathbf{c}|^{2} + 2\mathbf{a} \cdot \mathbf{b} + 2\mathbf{b} \cdot \mathbf{c} + 2\mathbf{c} \cdot \mathbf{a} = 0$$

$$\Rightarrow 1 + 1 + 1 + 2(\mathbf{a} \cdot \mathbf{b} + \mathbf{b} \cdot \mathbf{c} + \mathbf{c} \cdot \mathbf{a}) = 0$$

$$\Rightarrow \mathbf{a} \cdot \mathbf{b} + \mathbf{b} \cdot \mathbf{c} + \mathbf{c} \cdot \mathbf{a} = -\frac{3}{2}$$

**Example 7.** If **a**, **b** and **c** are mutually perpendicular vectors of equal magnitudes, then find the angle between the vectors **a** and **a**+**b**+**c**.

**Sol.** Let  $\theta$  be the angle between the vectors **a** and **a** + **b** + **c**.

Then, 
$$\cos \theta = \frac{\mathbf{a} \cdot (\mathbf{a} + \mathbf{b} + \mathbf{c})}{|\mathbf{a}| |\mathbf{a} + \mathbf{b} + \mathbf{c}|}$$
$$= \frac{\mathbf{a} \cdot \mathbf{a} + \mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c}}{|\mathbf{a}| |\mathbf{a} + \mathbf{b} + \mathbf{c}|}$$
$$= \frac{|\mathbf{a}|^2}{|\mathbf{a}| |\mathbf{a} + \mathbf{b} + \mathbf{c}|}$$

[:  $\mathbf{a} \cdot \mathbf{b} = \mathbf{a} \cdot \mathbf{c} = 0$  as  $\mathbf{a}, \mathbf{b}, \mathbf{c}$  are mutually perpendicular vectors]

$$=\frac{|\mathbf{a}|}{|\mathbf{a}+\mathbf{b}+\mathbf{c}|} \qquad ...(i)$$

Now consider,

$$|\mathbf{a} + \mathbf{b} + \mathbf{c}|^{2} = (\mathbf{a} + \mathbf{b} + \mathbf{c}) \cdot (\mathbf{a} + \mathbf{b} + \mathbf{c})$$

$$= |\mathbf{a}|^{2} + |\mathbf{b}|^{2} + |\mathbf{c}|^{2} + 2(\mathbf{a} \cdot \mathbf{b} + \mathbf{b} \cdot \mathbf{c} + \mathbf{c} \cdot \mathbf{a})$$

$$= 3|\mathbf{a}|^{2} + 2(0) = 3|\mathbf{a}|^{2}$$

$$[\because |\mathbf{a}| = |\mathbf{b}| = |\mathbf{c}| \text{ and } \mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{c} = \mathbf{c} \cdot \mathbf{a} = 0]$$

$$|\mathbf{a} + \mathbf{b} + \mathbf{c}| = \sqrt{3} |\mathbf{a}|$$

From Eq. (i), we get

$$\cos \theta = \frac{1}{\sqrt{3}}$$

$$\Rightarrow \qquad \theta = \cos^{-1} \frac{1}{\sqrt{3}}$$

**Example 8.** If the vectors  $\mathbf{a} = (c \log_2 x) \,\hat{\mathbf{i}} - 6 \,\hat{\mathbf{j}} + 3 \,\hat{\mathbf{k}}$  and  $\mathbf{b} = (\log_2 x) \,\hat{\mathbf{i}} + 2 \,\hat{\mathbf{j}} + (2c \log_2 x) \,\hat{\mathbf{k}}$  make an obtuse angle for any  $x \in (0, \infty)$ . Then, determine the interval to which c belongs.

**Sol.** For the vectors **a** and **b** to be inclined at an obtuse angle, we must have

$$\mathbf{a} \cdot \mathbf{b} < 0, \forall x \in (0, \infty)$$

$$\Rightarrow c(\log_2 x)^2 - 12 + 6c \log_2 x < 0, \forall x \in (0, \infty)$$

$$\Rightarrow cy^2 + 6cy - 12 < 0, \forall y \in R, \text{ where } y = \log_2 x$$

$$\Rightarrow c < 0 \text{ and } 36c^2 + 48c < 0,$$

$$(using ax^2 + bx + c < 0, \forall x \in R \text{ iff } a < 0 \text{ and } D < 0)$$

$$\Rightarrow c < 0 \text{ and } c (3c + 4) < 0 \Rightarrow c \in \left(-\frac{4}{3}, 0\right)$$

**Example 9.** If a+2b+3c=4, then find the least value of  $a^2+b^2+c^2$ .

**Sol.** Consider vectors  $\mathbf{p} = a\hat{\mathbf{i}} + b\hat{\mathbf{j}} + c\hat{\mathbf{k}}$  and  $\mathbf{q} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$ Now,  $\cos \theta = \frac{a + 2b + 3c}{\sqrt{a^2 + b^2 + c^2} \sqrt{1^2 + 2^2 + 3^2}}$   $\Rightarrow \cos^2 \theta = \frac{(a + 2b + 3c)^2}{14(a^2 + b^2 + c^2)} \le 1$  [::  $\cos^2 \theta \le 1$ ]  $\Rightarrow a^2 + b^2 + c^2 \ge \frac{(a + 2b + 3c)^2}{14} = \frac{16}{14} = \frac{8}{7}$ Hence, least value of  $a^2 + b^2 + c^2$  is  $\frac{8}{7}$ .

**Example 10.** Find the unit vector which makes an angle of  $45^{\circ}$  with the vector  $2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$  and an angle of  $60^{\circ}$  with the vector  $\hat{\mathbf{i}} - \hat{\mathbf{k}}$ .

**Sol.** Let the unit vector be  $\mathbf{c} = c_1 \hat{\mathbf{i}} + c_2 \hat{\mathbf{j}} + c_3 \hat{\mathbf{k}}$  so that; it makes an angle of 45° with  $2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$ .

$$\Rightarrow \frac{2c_1 + 2c_2 - c_3}{3} = \cos 45^{\circ} \qquad (:|\hat{\mathbf{c}}| = 1)$$

$$\Rightarrow$$
  $2c_1 + 2c_2 - c_3 = \frac{3}{\sqrt{2}}$  ...(i)

Also, it makes an angle of  $60^{\circ}$  with  $\hat{\mathbf{j}} - \hat{\mathbf{k}}$ .

$$\Rightarrow \frac{c_2 - c_3}{\sqrt{2}} = \cos 60^{\circ} \quad (:|\hat{\mathbf{j}} - \hat{\mathbf{k}}| = \sqrt{2} \text{ and } |\hat{\mathbf{c}}| = 1)$$

$$\Rightarrow c_2 - c_3 = \frac{\sqrt{2}}{2} \qquad ...(ii)$$

$$\Rightarrow$$
  $c_1^2 + c_2^2 + c_3^2 = 1$  ...(iii)

(using 
$$|\mathbf{c}| = |c_1\hat{\mathbf{i}} + c_2\hat{\mathbf{j}} + c_3\hat{\mathbf{k}}| = 1$$
)

From Eq. (ii), 
$$c_2 = \frac{1}{\sqrt{2}} + c_3$$
 and from Eq. (i),  $c_1 = \frac{-c_3}{2} + \frac{1}{2\sqrt{2}}$ 

On substituting in Eq. (iii), we get

$$\frac{c_3^2}{4} + \frac{1}{2} + \frac{2c_3}{\sqrt{2}} + \frac{1}{8} - \frac{c_3}{2\sqrt{2}} + c_3^2 + c_3^2 = 1$$

$$\Rightarrow \frac{9}{4}c_3^2 + \frac{3c_3}{2\sqrt{2}} + \frac{5}{8} = 1 \Rightarrow c_3 = -\frac{1}{\sqrt{2}}, \frac{1}{3\sqrt{2}}$$

Hence, the required vectors are  $\left(\frac{1}{\sqrt{2}}, 0, -\frac{1}{\sqrt{2}}\right)$  and

$$\left(\frac{1}{3\sqrt{2}}, \frac{4}{3\sqrt{2}}, \frac{1}{3\sqrt{2}}\right).$$

**Example 11.** Show that the median to the base of an isosceles triangle is perpendicular to base.

**Sol.** Let ABC be an isosceles triangle in which AB = AC.

Let *A* be the origin of reference and let

$$AB = b, AC = c$$

Let *D* be the middle point of **BC**.  
Then, 
$$\mathbf{AD} = \frac{\mathbf{b} + \mathbf{c}}{2}$$
  
Now,  $\mathbf{BC} = \mathbf{c} - \mathbf{b}$   

$$\therefore \mathbf{AD} \cdot \mathbf{BC} = \left(\frac{\mathbf{b} + \mathbf{c}}{2}\right) \cdot (\mathbf{c} - \mathbf{b})$$

$$= \frac{1}{2} (|\mathbf{c}|^2 - |\mathbf{b}|^2) = \frac{1}{2} (|\mathbf{AC}|^2 - |\mathbf{AB}|^2)$$

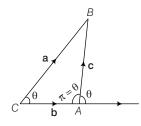

$$= \frac{1}{2} (0) = 0$$

Hence, median to the base of an isosceles triangle is perpendicular to base.

**Example 12.** Using vector method, prove that in a triangle,  $a^2 = b^2 + c^2 - 2bc \cos A$  (cosine law).

**Sol.** In  $a \Delta ABC$ ,

Let 
$$AB = c$$
,  $BC = a$ ,  $CA = b$   
 $\therefore a + b + c = 0$ 

We have, 
$$\mathbf{a} = -(\mathbf{b} + \mathbf{c})$$
  

$$\therefore |\mathbf{a}| = |-(\mathbf{b} + \mathbf{c})| \Rightarrow |\mathbf{a}|^2 = |\mathbf{b} + \mathbf{c}|^2$$

$$\Rightarrow |\mathbf{a}|^2 = |\mathbf{b}|^2 + |\mathbf{c}|^2 + 2\mathbf{b} \cdot \mathbf{c}$$

$$\Rightarrow |\mathbf{a}^2| = |\mathbf{b}|^2 + |\mathbf{c}|^2 + 2|\mathbf{b}| |\mathbf{c}| |\cos(\pi - A)|$$

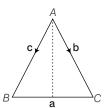

Since, angle between **b** and  $\mathbf{c}$  = The angle between CAproduced and AB

$$a^2 = b^2 + c^2 - 2bc \cos A$$

**Example 13.** Using vector method, prove that in a triangle,  $a = b \cos C + c \cos B$  (projection formula).

**Sol.** In a  $\triangle$  *ABC*,

Let 
$$AB = c$$
,  $BC = a$ ,  $CA = b$   
 $\therefore a + b + c = 0$ 

We have, |a| = |-(b + c)|

$$\therefore \mathbf{a} \cdot \mathbf{a} = -(\mathbf{b} + \mathbf{c}) \cdot \mathbf{a}$$

or 
$$|\mathbf{a}|^2 = -\mathbf{b} \cdot \mathbf{a} - \mathbf{c} \cdot \mathbf{a}$$

$$= -|\mathbf{b}| |\mathbf{a}| \cos(\pi - C) - |\mathbf{c}| |\mathbf{a}| \cos(\pi - B)$$

Since, the angle between **b** and  $\mathbf{a} = (\pi - C)$  and angle between  $\mathbf{c}$  and  $\mathbf{a} = (\pi - \mathbf{B})$ 

$$\therefore a^2 = ab\cos C + ac\cos B$$

$$\Rightarrow a = b \cos C + c \cos B$$

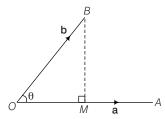

## Components of a Vector Along and Perpendicular to Another Vector

Let **a** and **b** be two vectors represented by **OA** and **OB** and let  $\theta$  be the angle between **a** and **b**. Draw  $MB \perp OA$ , shown as

$$b = OM + MB$$

$$\Rightarrow OM = (OM)\mathbf{a} = (OB\cos\theta)\mathbf{a} = (|\mathbf{b}|\cos\theta)\mathbf{a}$$

$$= \left( \left| \mathbf{b} \right| \frac{(\mathbf{a} \cdot \mathbf{b})}{\left| \mathbf{a} \right|^2} \right) \mathbf{a}$$

$$= \left(\frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|}\right) \mathbf{a} = \frac{\mathbf{a} \cdot \mathbf{b} \, \mathbf{a}}{|\mathbf{a}||\mathbf{a}|} = \left(\frac{\mathbf{a} - \mathbf{b}}{|\mathbf{a}|^2}\right) \mathbf{a}$$

$$b = OM + MB$$

$$MB = b - OM = b - \left(\frac{a \cdot b}{|a|^2}\right)a$$

Thus, the components of **b** along and perpendicular to **a**  $\operatorname{are}\left(\frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|^2}\right)\mathbf{a}$  and  $\mathbf{a}-\left(\frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|^2}\right)\mathbf{a}$  respectively.

**Example 14.** If  $\mathbf{a} = 4\hat{\mathbf{i}} + 6\hat{\mathbf{j}}$  and  $\mathbf{b} = 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$ , then find the component of **a** along **b**.

**Sol.** The component of vector **a** along **b** is  $\frac{(\mathbf{a} \cdot \mathbf{b})}{|\mathbf{b}|^2}$ 

$$=\frac{18}{25}\left(3\hat{\mathbf{j}}+4\hat{\mathbf{k}}\right)$$

**Example 15.** Express the vector  $\mathbf{a} = 5\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$  as sum of two vectors such that one is parallel to the vector  $\mathbf{b} = 3\mathbf{i} + \mathbf{k}$  and the other is perpendicular to  $\mathbf{b}$ .

Sol. Required vectors are

$$\left(\frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{b}|^2}\right) \mathbf{b} \text{ and } \mathbf{a} - \left(\frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{b}|^2}\right) \mathbf{b}$$
Clearly, 
$$\left(\frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{b}|^2}\right) \mathbf{b} = 2(3\hat{\mathbf{i}} + \hat{\mathbf{k}}) = 6\hat{\mathbf{i}} + 2\hat{\mathbf{k}} \text{ and so,}$$

$$\mathbf{a} - \left(\frac{\mathbf{a} - \mathbf{b}}{|\mathbf{b}|^2}\right) \mathbf{b} = (5\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 5\hat{\mathbf{k}}) - (6\hat{\mathbf{i}} + 2\hat{\mathbf{k}})$$

$$= -\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$$
Note that 
$$(6\hat{\mathbf{i}} + 2\hat{\mathbf{k}}) + (-\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})$$

$$= 5\hat{\mathbf{i}} - 2\hat{\mathbf{i}} + 5\hat{\mathbf{k}} - 2\hat{\mathbf{k}}$$

# **Application of Dot Product in Mechanics** (Work done)

A force acting on a particle is said to do work, if the particle is displaced in a direction which is not perpendicular to force.

Let a particle be placed at O and a force f represented by **OB** be acting on the particle at O. Due to the application of force f, the particle is displaced in the direction of OA. Let **OA** be the displacement.

Then, the component of OA in the direction of force fis,  $|\mathbf{OA}|\cos\theta$ 

Work done = 
$$|\mathbf{f}| |\mathbf{O}\mathbf{A}| \cos \theta = \mathbf{f} \cdot \mathbf{O}\mathbf{A}$$
  
=  $\mathbf{f} \cdot \mathbf{d}$ , where  $\mathbf{d} = \mathbf{O}\mathbf{A}$ 

 $\therefore$  Work done = (Force) · (Displacement)

1. The work done by the resultant of a number of forces  $\mathbf{f}_1\mathbf{f}_2$ ,  $\mathbf{f}_3$ , ...  $\mathbf{f}_n$  in a displacement **d** of a particle is equal to the sum of work done by the forces separately

i.e. Work done = 
$$\mathbf{f}_1 \cdot \mathbf{d} + \mathbf{f}_2 \cdot \mathbf{d} + \dots + \mathbf{f}_n \cdot \mathbf{d}$$
  
=  $(\mathbf{f}_1 + \mathbf{f}_2 + \dots + \mathbf{f}_n) \cdot \mathbf{d}$   
=  $\mathbf{R} \cdot \mathbf{d}$  where,  $\mathbf{R} = \mathbf{f}_1 + \mathbf{f}_2 + \dots + \mathbf{f}_n$ 

2. The work done by a force f when its point of application experiences a number of consecutive displacements

 $\mathbf{d}_1$ ,  $\mathbf{d}_2$ ,  $\mathbf{d}_3$ ..., $\mathbf{d}_n$ , is equal to the work done by the forces in single displacement from the beginning to end.

*i.e.*, Work done =  $\mathbf{f} \cdot (\mathbf{d}_1 + \mathbf{d}_2 + .... + \mathbf{d}_n)$ 

= The work done by the force  $\mathbf{f}$  in the single displacement from the beginning to end

**Example 16.** Two forces  $\mathbf{f}_1 = 3\mathbf{i} - 2\mathbf{j} + \mathbf{k}$  and  $\mathbf{f}_2 = \hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$  acting on a particle at A move it to B. Find the work done if the position vector of A and B are -2i + 5k and 3i - 7j + 2k.

**Sol.** Let  ${\bf R}$  be the resultant of two forces  ${\bf f}_1$  and  ${\bf f}_2$  and  ${\bf d}$  be the

Then, 
$$\mathbf{R} = (3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}) + (\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 5\hat{\mathbf{k}})$$

$$= 4\hat{\mathbf{i}} + \hat{\mathbf{j}} - 4\hat{\mathbf{k}}$$
and 
$$\mathbf{d} = (3\hat{\mathbf{i}} - 7\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) - (-2\hat{\mathbf{i}} + 5\hat{\mathbf{k}}) = 5\hat{\mathbf{i}} - 7\hat{\mathbf{j}} - 3\hat{\mathbf{k}}$$

$$\therefore \text{ The total work done} = \text{ The work done by resultant}$$

$$= \mathbf{R} \cdot \mathbf{d} = (4\hat{\mathbf{i}} + \hat{\mathbf{j}} - 4\hat{\mathbf{k}}) \cdot (5\hat{\mathbf{i}} - 7\hat{\mathbf{j}} - 3\hat{\mathbf{k}})$$

$$= 20 - 7 + 12 = 25 \text{ units}$$

**Example 17.** Forces of magnitudes 5 and 3 units acting in the directions  $6\mathbf{i} + 2\mathbf{j} + 3\mathbf{k}$  and  $3\mathbf{i} - 2\mathbf{j} + 6\mathbf{k}$ , respectively act on a particle which is displaced from the point (2, 2, -1) and (4, 3, 1). Find the work done by the forces.

**Sol.** Let **R** be the resultant of two forces and **d** be the displacement.

Then,

and

$$\mathbf{R} = 5\frac{(6\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})}{\sqrt{36 + 4 + 9}} + 3\frac{(3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 6\hat{\mathbf{k}})}{\sqrt{9 + 4 + 36}}$$
$$= \frac{1}{7}(39\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 33\hat{\mathbf{k}})$$
$$\mathbf{d} = (4\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + \hat{\mathbf{k}}) - (2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}) = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

 $\therefore$  Total work done =  $\mathbf{R} \cdot \mathbf{d} = \frac{1}{7}(78 + 4 + 66)$ 

$$=\frac{148}{7} \text{ units}$$

# Vector or Cross Product of Two Vectors, Area of Parallelogram and Triangle, Moment of a Force and Couple, Rotation About an Axis

## **Vector or Cross Product** of Two Vectors

Let **a** and **b** be two non-zero, non- parallel vectors. Then the vector product  $\mathbf{a} \times \mathbf{b}$ , in that order, is defined as a vector whose magnitude

$$|\mathbf{a}||\mathbf{b}|\sin\theta$$

where  $\theta$  is the angle between **a** and **b**, whose direction is perpendicular to the plane of **a** and **b** in such a way that **a**, **b** and this direction constitute a right handed system.

In other words,  $\mathbf{a} \times \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \sin \theta \mathbf{n}$ , where  $\theta$  is the angle between **a** and **b**,  $\hat{\mathbf{n}}$  is a unit vector perpendicular to the plane of **a** and **b** such that **a**, **b** and *n* form a right handed system.

## **Properties of Vector Product**

- (i) Vector product is not commutative i.e., if  $\mathbf{a}$  and  $\mathbf{b}$  are any two vectors, then  $\mathbf{a} \times \mathbf{b} \neq \mathbf{b} \times \mathbf{a}$ , however  $\mathbf{a} \times \mathbf{b} = -(\mathbf{b} \times \mathbf{a}).$
- (ii) Vector product is not associative, i.e.  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) \neq (\mathbf{a} \times \mathbf{b}) \times \mathbf{c}$
- (iii) If **a** and **b** are two vectors and *m* is a scalar, then  $m\mathbf{a} \times \mathbf{b} = m (\mathbf{a} \times \mathbf{b}) = \mathbf{a} \times m\mathbf{b}$
- (iv) If **a** and **b** are two vectors and *m* and *n* are scalars, then  $m\mathbf{a} \times n\mathbf{b} = mn(\mathbf{a} \times \mathbf{b}) = m(\mathbf{a} \times \mathbf{b}) = n(m\mathbf{a} \times \mathbf{b})$
- (v) Distributivity of vector product over vector addition. Let **a**, **b** and **c** be any three vectors. Then,
  - (a)  $\mathbf{a} \times (\mathbf{b} + \mathbf{c}) = \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c}$ (left distributivity)
  - (b)  $(\mathbf{b} + \mathbf{c}) \times \mathbf{a} = \mathbf{b} \times \mathbf{a} + \mathbf{c} \times \mathbf{a}$ (right distributivity)
- (vi) For any three vectors **a**, **b** and **c**, we have  $\mathbf{a} \times (\mathbf{b} - \mathbf{c}) = \mathbf{a} \times \mathbf{b} - \mathbf{a} \times \mathbf{c}$ .
- (vii) The vector product of any vector (zero or non-zero) with zero vector is a zero vector i.e.

$$\mathbf{a} \times \mathbf{0} = \mathbf{0} \times \mathbf{a} = \mathbf{0}$$

- (viii) The vector product of two non-zero vectors is zero vector iff they are parallel (collinear) i.e.  $\mathbf{a} \times \mathbf{b} = \mathbf{0}$  $\Leftrightarrow$  **a** || **b**, **a** and **b** are non-zero vectors. It follows from the above property that  $\mathbf{a} \times \mathbf{a} = \mathbf{0}$  for every non-zero vector a, which in turn implies that
- (ix) Vector product of orthonormal triad of unit vectors  $\hat{\mathbf{i}},\,\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  using the definition of the vector product obtain

$$\begin{split} \hat{\mathbf{i}} \times \hat{\mathbf{j}} &= \hat{\mathbf{k}}, \, \hat{\mathbf{j}} \times \hat{\mathbf{k}} = \hat{\mathbf{i}}, \, \hat{\mathbf{k}} \times \hat{\mathbf{i}} = \hat{\mathbf{j}}, \\ \hat{\mathbf{j}} \times \hat{\mathbf{i}} &= -\hat{\mathbf{k}}, \, \hat{\mathbf{k}} \times \hat{\mathbf{j}} = -\hat{\mathbf{i}}, \, \hat{\mathbf{i}} \times \hat{\mathbf{k}} = -\hat{\mathbf{j}} \end{split}$$

(x) Lagrange's identity If a, b are any two vectors, then  $|\mathbf{a} \times \mathbf{b}|^2 = |\mathbf{a}|^2 |\mathbf{b}|^2 - (\mathbf{a} \cdot \mathbf{b})^2$ or  $|\mathbf{a} \times \mathbf{b}|^2 + (\mathbf{a} \cdot \mathbf{b})^2 = |\mathbf{a}|^2 |\mathbf{b}|^2$ 

## **Vector Product in Terms** of Components

 $\hat{\mathbf{i}} \times \hat{\mathbf{i}} = \hat{\mathbf{j}} \times \hat{\mathbf{j}} = \hat{\mathbf{k}} \times \hat{\mathbf{k}} = \mathbf{0}.$ 

If  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$  and  $\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$ Then,  $a \times b = (a_2b_3 - a_3b_2)\hat{\mathbf{i}} - (a_1b_3 - a_3b_1)\hat{\mathbf{j}}$ 

$$+(a_1b_2 - a_2b_1)\hat{\mathbf{k}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}$$

**Example 18.** If  $\mathbf{a} = 2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$  and  $\mathbf{b} = m\hat{\mathbf{i}} + n\hat{\mathbf{j}} + 12\hat{\mathbf{k}}$ and  $\mathbf{a} \times \mathbf{b} = \mathbf{0}$ . Then, find the values of m and n.

Sol. Clearly, 
$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & 3 & -5 \\ m & n & 12 \end{vmatrix}$$
  
=  $\hat{\mathbf{i}} (36 + 5n) - \hat{\mathbf{j}} (24 + 5m) + \hat{\mathbf{k}} (2n - 3m)$   
Since,  $\mathbf{a} \times \mathbf{b} = \mathbf{0}$   
∴  $(36 + 5n) \hat{\mathbf{i}} - (24 + 5m) \hat{\mathbf{j}} + (2n - 3m) \hat{\mathbf{k}} = 0 \hat{\mathbf{i}} + 0 \hat{\mathbf{j}} + 0 \hat{\mathbf{k}}$   
On comparing the coefficients of  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$ , we get  
 $36 + 5n = 0, -(24 + 5m) = 0$  and  $2n - 3m = 0$   
⇒  $n = -\frac{36}{5}$  and  $m = -\frac{24}{5}$ 

### **Example 19.** Show that $(\mathbf{a} - \mathbf{b}) \times (\mathbf{a} + \mathbf{b}) = 2(\mathbf{a} \times \mathbf{b})$

**Sol.** Consider, 
$$(\mathbf{a} - \mathbf{b}) \times (\mathbf{a} + \mathbf{b}) = (\mathbf{a} - \mathbf{b}) \times \mathbf{a} + (\mathbf{a} - \mathbf{b}) \times \mathbf{b}$$
 [By distributivity of vector product over vector addition]

 $= \mathbf{a} \times \mathbf{a} - \mathbf{b} \times \mathbf{a} + \mathbf{a} \times \mathbf{b} - \mathbf{b} \times \mathbf{b}$ 

[Again, by distributivity of vector product over vector addition]

$$= 0 + \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{b} - 0 \quad [\because \mathbf{a} \times \mathbf{b} = -(\mathbf{b} \times \mathbf{a})]$$
  
= 2 (\mathbf{a} \times \mathbf{b}) Hence Proved

## **Example 20.** If a is any vector, then

$$(\mathbf{a} \times \hat{\mathbf{i}})^2 + (\mathbf{a} \times \hat{\mathbf{j}})^2 + (\mathbf{a} \times \hat{\mathbf{k}})^2$$
 is equal to

(a)  $| \mathbf{a} |^2$ 

(c)  $3 | \mathbf{a} |^2$ 

(d)  $2 | \mathbf{a} |^2$ 

**Sol.** (d) Let 
$$\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$$

$$\therefore \mathbf{a} \times \hat{\mathbf{i}} = (a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}) \times \hat{\mathbf{i}} = -a_2 \hat{\mathbf{k}} + a_3 \hat{\mathbf{j}}$$

$$(\mathbf{a} \times \hat{\mathbf{i}})^2 = (\mathbf{a} \times \hat{\mathbf{i}}) \cdot (\mathbf{a} \times \hat{\mathbf{i}})$$

$$= (-a_2 \hat{\mathbf{k}} + a_3 \hat{\mathbf{j}}) \cdot (-a_2 \hat{\mathbf{k}} + a_3 \hat{\mathbf{j}}) = a_2^2 + a_3^2$$
Similarly,  $(\mathbf{a} \times \hat{\mathbf{j}})^2 = a_3^2 + a_1^2$ 
and  $(\mathbf{a} \times \hat{\mathbf{k}})^2 = a_1^2 + a_2^2$ 

$$\therefore (\mathbf{a} \times \hat{\mathbf{i}})^2 + (\mathbf{a} \times \hat{\mathbf{j}})^2 + (\mathbf{a} \times \hat{\mathbf{k}})^2$$

$$= 2(a_1^2 + a_2^2 + a_3^2) = 2 |\mathbf{a}|^2$$

**Example 21.** If  $\mathbf{a} \cdot \mathbf{b} = 0$  and  $\mathbf{a} \times \mathbf{b} = 0$ , prove that a = 0 or b = 0.

**Sol.** Given, 
$$\mathbf{a} \cdot \mathbf{b} = 0$$
 and  $\mathbf{a} \times \mathbf{b} = 0$ 

Now,  $\mathbf{a} \cdot \mathbf{b} = 0 \Rightarrow \mathbf{a} = 0 \text{ or } \mathbf{b} = 0 \text{ or } \mathbf{a} \perp \mathbf{b}$ and  $\mathbf{a} \times \mathbf{b} = 0 \Rightarrow \mathbf{a} = 0 \text{ or } \mathbf{b} = 0 \text{ or } \mathbf{a} \mid \mid \mathbf{b}$ 

Since,  $\mathbf{a} \perp \mathbf{b}$  and  $\mathbf{a} \parallel \mathbf{b}$  can never hold simultaneously.

$$\begin{array}{ccc} \therefore & \mathbf{a} \cdot \mathbf{b} = 0 \text{ and } \mathbf{a} \times \mathbf{b} = 0 \\ \Rightarrow & \mathbf{a} = 0 \text{ or } \mathbf{b} = 0 \end{array}$$

**Example 22.** If **a**, **b** and **c** are vectors such that  $\mathbf{a} \cdot \mathbf{b} = \mathbf{a} \cdot \mathbf{c}$ ,  $\mathbf{a} \times \mathbf{b} = \mathbf{a} \times \mathbf{c}$  and  $\mathbf{a} \neq 0$ , then show that  $\mathbf{b} = \mathbf{c}$ 

**Sol.**
$$\mathbf{a} \cdot \mathbf{b} = \mathbf{a} \cdot \mathbf{c}$$
 and  $\mathbf{a} \neq 0$ 

$$\Rightarrow \qquad \mathbf{a} \cdot \mathbf{b} - \mathbf{a} \cdot \mathbf{c} = 0 \text{ and } \mathbf{a} \neq 0$$

$$\Rightarrow \qquad \mathbf{a} \cdot (\mathbf{b} - \mathbf{c}) = 0 \text{ and } \mathbf{a} \neq 0$$

$$\Rightarrow \qquad \mathbf{a} \perp (\mathbf{b} - \mathbf{c}) \text{ or } \mathbf{b} = \mathbf{c} \qquad \dots(i)$$
Again,
$$\mathbf{a} \times \mathbf{b} = \mathbf{a} \times \mathbf{c} \text{ and } \mathbf{a} \neq 0$$

$$\Rightarrow \qquad \mathbf{a} \times (\mathbf{b} - \mathbf{c}) = 0 \text{ and } \mathbf{a} \neq 0$$

$$\Rightarrow \qquad \mathbf{a} \mid |(\mathbf{b} - \mathbf{c}) = 0 \text{ and } \mathbf{b} = \mathbf{c} \qquad \dots(ii)$$

∴ From Eqs. (i) and (ii), we have

 $\mathbf{b} = \mathbf{c}$ 

[as a cannot be both parallel and perpendicular to  $(\mathbf{b} - \mathbf{c})$ 

...(ii)

**Example 23.** If **a**,**b** and **c** are three non-zero vectors such that  $\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = 0$  and  $\mathbf{b}$  and  $\mathbf{c}$  are not parallel vectors, prove that  $\mathbf{a} = \lambda \mathbf{b} + \mu \mathbf{c}$  where  $\lambda$  and  $\mu$  are scalar.

**Sol.** We have,  $\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = 0$ 

$$\Rightarrow \qquad \mathbf{a} = 0 \text{ or } \mathbf{b} \times \mathbf{c} = 0 \text{ or } \mathbf{a} \perp (\mathbf{b} \times \mathbf{c})$$

$$\Rightarrow \qquad \mathbf{a} = 0 \text{ or } \mathbf{b} \mid\mid \mathbf{c} \text{ or } \mathbf{a} \perp (\mathbf{b} \times \mathbf{c})$$
But  $\mathbf{a} \neq 0 \text{ and } \mathbf{b} \neq \mathbf{c}$ 

$$\therefore \qquad \mathbf{a} \perp (\mathbf{b} \times \mathbf{c})$$

$$\Rightarrow \qquad \mathbf{a} \text{ lies in the plane of } \mathbf{b} \text{ and } \mathbf{c}.$$

**a**, **b** and **c** are coplanar.  $\Rightarrow$ 

 $a = \lambda b + \mu c$ 

### **Example 24.** If $\mathbf{a} \times \mathbf{b} = \mathbf{a} \times \mathbf{c}$ , $\mathbf{a} \neq 0$ , show that $\mathbf{b} = \mathbf{c} + t\mathbf{a}$ for some scalar t.

**Sol.** We have, 
$$\mathbf{a} \times \mathbf{b} = \mathbf{a} \times \mathbf{c}$$

$$\Rightarrow \qquad \mathbf{a} \times \mathbf{b} - \mathbf{a} \times \mathbf{c} = 0$$

$$\Rightarrow \qquad \mathbf{a} \times (\mathbf{b} - \mathbf{c}) = 0$$

$$\Rightarrow \qquad \mathbf{a} = 0 \text{ or } (\mathbf{b} - \mathbf{c}) = 0 \text{ or } \mathbf{a} \mid \mid (\mathbf{b} - \mathbf{c})$$

$$\Rightarrow \qquad \mathbf{a} \mid \mid (\mathbf{b} - \mathbf{c}) \qquad (\because \mathbf{a} \neq 0 \text{ and } \mathbf{b} \neq 0)$$

$$\Rightarrow \qquad \mathbf{b} - \mathbf{c} = t\mathbf{a} \qquad (\text{for some scalar } t)$$

$$\Rightarrow \qquad \mathbf{b} = \mathbf{c} + t\mathbf{a}$$

(ii) 
$$(1 + |\mathbf{u}|^2) (1 + |\mathbf{v}|^2) = (1 - \mathbf{u} \cdot \mathbf{v})^2 + |\mathbf{u} + \mathbf{v} + (\mathbf{u} \times \mathbf{v})|^2$$

**Sol.** (i) To show

Let  $\theta$  be the angle between **u** and **v**.

$$\Rightarrow \mathbf{u} \cdot \mathbf{v} = uv \cos \theta$$
and
$$|\mathbf{u} \times \mathbf{v}| = uv \sin \theta$$

$$\Rightarrow (\mathbf{u} \cdot \mathbf{v})^2 + |\mathbf{u} \times \mathbf{v}|^2 = u^2 v^2 \cos^2 \theta + u^2 v^2 \sin^2 \theta$$

(ii) Taking RHS  $(1 - \mathbf{u} \cdot \mathbf{v})^2 + |\mathbf{u} + \mathbf{v} + (\mathbf{u} \times \mathbf{v})|^2$

$$\Rightarrow 1 + |\mathbf{u}|^2 |\mathbf{v}|^2 + |\mathbf{u}|^2 + |\mathbf{v}|^2$$
$$= (1 + |\mathbf{u}|^2)(1 + |\mathbf{v}|^2) = LHS$$

## **Angle between Two Vectors**

If  $\theta$  is the angle between  $\mathbf{a}$  and  $\mathbf{b}$ , then  $\sin \theta = \frac{|\mathbf{a} \times \mathbf{b}|}{|\mathbf{a}||\mathbf{b}|}$ .

### Expression for $\sin \theta$

If  $\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}, \mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$  and  $\theta$  be angle between **a** and **b**, then

$$\sin^2 \theta = \frac{(a_2b_3 - a_3b_2)^2 + (a_1b_3 - a_3b_1)^2 + (a_1b_2 - a_2b_1)^2}{(a_1^2 + a_2^2 + a_3^2)(b_1^2 + b_2^2 + b_3^2)}$$

**Example 26.** The sine of the angle between the vector  $\mathbf{a} = 3\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\mathbf{b} = 2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$  is

(a) 
$$\sqrt{\frac{74}{99}}$$

(b) 
$$\sqrt{\frac{25}{99}}$$

(c) 
$$\sqrt{\frac{37}{99}}$$

(d) 
$$\frac{5}{\sqrt{4}}$$

**Sol.** (a) 
$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 3 & 1 & 1 \\ 2 & -2 & 1 \end{vmatrix} = 3\hat{\mathbf{i}} - \hat{\mathbf{j}} - 8\hat{\mathbf{k}}$$

$$\sin \theta = \frac{|\mathbf{a} \times \mathbf{b}|}{|\mathbf{a}||\mathbf{b}|} = \frac{\sqrt{74}}{\sqrt{11} \cdot \sqrt{9}} = \sqrt{\frac{74}{99}}$$

**Example 27.** If |a| = 2, |b| = 5 and  $|a \times b| = 8$ , then find the value of  $\mathbf{a} \cdot \mathbf{b}$ .

**Sol.** We have, 
$$|\mathbf{a}| = 2$$
,  $|\mathbf{b}| = 5$ 

$$|\mathbf{a} \times \mathbf{b}| = 8.$$

Let  $\theta$  be the angle between **a** and **b**.

Then, 
$$\sin \theta = \frac{|\mathbf{a} \times \mathbf{b}|}{|\mathbf{a}||\mathbf{b}|} = \frac{8}{2 \times 5} = \frac{4}{5}$$

Now, 
$$\cos \theta = \pm \sqrt{1 - \sin^2 \theta}$$

$$=\pm\sqrt{1-\frac{16}{25}}=\pm\frac{3}{5}$$

$$\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| \mathbf{b} | \cos \theta = \pm \left(2 \cdot 5 \cdot \frac{3}{5}\right) = \pm 6$$

### Vector Normal to the Plane of Two Given Vectors

If **a** and **b** are two non-zero, non-parallel vectors and let  $\theta$ be the angle between them.  $\mathbf{a} \times \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \sin \theta \,\hat{\mathbf{n}}$ , where  $\hat{\mathbf{n}}$ is a unit vector perpendicular to the plane of  $\mathbf{a}$  and  $\mathbf{b}$  such that a, b,  $\hat{n}$  form a right handed system.

$$\Rightarrow$$

$$(\mathbf{a} \times \mathbf{b}) = |\mathbf{a} \times \mathbf{b}| \hat{\mathbf{n}}$$

$$\Rightarrow$$

$$\hat{\mathbf{n}} = \frac{\mathbf{a} \times \mathbf{b}}{|\mathbf{a} \times \mathbf{b}|}$$

Thus,  $\hat{\boldsymbol{n}} = \frac{\boldsymbol{a} \times \boldsymbol{b}}{\mid \boldsymbol{a} \times \boldsymbol{b} \mid}$  is a unit vector perpendicular to the

plane of **a** and **b**. Note that  $-\frac{\mathbf{a} \times \mathbf{b}}{|\mathbf{a} \times \mathbf{b}|}$  is also a unit vector

perpendicular to the plane of a and b. Vectors of magnitude ' $\lambda$ ' normal to the plane of **a** and **b** are given by

$$\pm \frac{\lambda (\mathbf{a} \times \mathbf{b})}{|\mathbf{b} \times \mathbf{b}|}$$

**Example 28.** The unit vector perpendicular to the vectors  $6\mathbf{i} + 2\mathbf{j} + 3\mathbf{k}$  and  $3\mathbf{i} - 6\mathbf{j} - 2\mathbf{k}$ , is

(a) 
$$\frac{2\hat{i} - 3\hat{j} + 6\hat{k}}{7}$$
 (b)  $\frac{2\hat{i} - 3\hat{j} - 6\hat{k}}{7}$ 

(b) 
$$\frac{2\hat{i} - 3\hat{j} - 6\hat{k}}{7}$$

(c) 
$$\frac{2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}}}{7}$$

(c) 
$$\frac{2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}}}{7}$$
 (d)  $\frac{2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 6\hat{\mathbf{k}}}{7}$ 

**Sol.** (c) Let  $\mathbf{a} = 6\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  and  $\mathbf{b} = 3\hat{\mathbf{i}} - 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$ 

$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 6 & 2 & 3 \\ 3 & -6 & -2 \end{vmatrix}$$
$$= 14\hat{\mathbf{i}} + 21\hat{\mathbf{j}} - 42\hat{\mathbf{k}} = 7 (2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}})$$
$$|\mathbf{a} \times \mathbf{b}| = 7 |2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}}| = 7 \cdot 7$$

 $\therefore \frac{\mathbf{a} \times \mathbf{b}}{|\mathbf{a} \times \mathbf{b}|} = \frac{1}{7} (2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}})$ which is a unit vector perpendicular to **a** and **b**.

**Example 29.** Find unit vectors perpendicular to the plane determined by the points

$$P(1, -1, 2), Q(2, 0, -1)$$
 and  $R(0, 2, 1)$ 

Sol. Clearly, required unit vector is a unit vector perpendicular to the plane of PQ and PR.

Now,

$$PQ = (2\hat{\mathbf{i}} - \hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

$$= \hat{\mathbf{i}} + \hat{\mathbf{j}} - 3\hat{\mathbf{k}}$$

$$PR = (2\hat{\mathbf{j}} + \hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

$$= -\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - \hat{\mathbf{k}}$$

$$\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & 1 & -3 \end{vmatrix} = 8\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$

and  $\mathbf{PQ} \times \mathbf{PR} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & 1 & -3 \\ -1 & 3 & -1 \end{vmatrix} = 8\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$ 

.. Required unit vectors

$$= \pm \frac{\mathbf{PQ} \times \mathbf{PR}}{|\mathbf{PQ} \times \mathbf{PR}|} = \pm \frac{(8\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}})}{4\sqrt{6}}$$
$$= \pm \frac{1}{\sqrt{6}} (2\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}})$$

**Example 30.** Let A, B and C be unit vectors. Suppose  $\mathbf{A} \cdot \mathbf{B} = \mathbf{A} \cdot \mathbf{C} = 0$  and the angle between B and C is  $\frac{\pi}{\mu}$ . Then,

(a) 
$$\mathbf{A} = \pm 2 \ (\mathbf{B} \times \mathbf{C})$$

(b) 
$$\mathbf{A} = \pm \sqrt{2} \ (\mathbf{B} \times \mathbf{C})$$

(c) 
$$\mathbf{A} = \pm 3 (\mathbf{B} + \mathbf{C})$$

(d) 
$$\mathbf{A} = \pm \sqrt{3} (\mathbf{B} \times \mathbf{C})$$

**Sol.** (b) Since,  $\mathbf{A} \cdot \mathbf{B} = 0$ 

$$\Rightarrow$$
  $\mathbf{A} \perp \mathbf{B}$  and  $\mathbf{A} \cdot \mathbf{C} = 0$ 

$$\Rightarrow$$
  $A \perp C$ 

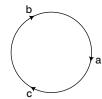

$$\mathbf{A} = \pm \frac{\mathbf{B} \times \mathbf{C}}{|\mathbf{B} \times \mathbf{C}|}$$

[∵ **A** is a unit vector perpendicular to both **B** and **C**]

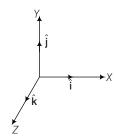

Here, 
$$|\mathbf{B} \times \mathbf{C}| = |\mathbf{B}| |\mathbf{C}| \sin \frac{\pi}{4}$$
$$= 1 \cdot 1 \cdot \frac{1}{\sqrt{2}} = \frac{1}{\sqrt{2}}$$
So, 
$$\mathbf{A} = \pm \frac{(\mathbf{B} \times \mathbf{C})}{\frac{1}{\sqrt{2}}} = \pm \sqrt{2} (\mathbf{B} \times \mathbf{C})$$

## Right Handed System and Left **Handed System of Vectors**

(i) Right handed system of vectors Three mutually perpendicular vectors **a**, **b** and **c** from a right handed system of vector iff  $\mathbf{a} \times \mathbf{b} = \mathbf{c}$ ,  $\mathbf{b} \times \mathbf{c} = \mathbf{a}$ ,  $\mathbf{c} \times \mathbf{a} = \mathbf{b}$ .

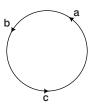

For example, the unit vectors  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  form a right handed system,  $\hat{\mathbf{i}} \times \hat{\mathbf{j}} = \hat{\mathbf{k}}$ ,  $\hat{\mathbf{j}} \times \hat{\mathbf{k}} = \hat{\mathbf{i}}$ ,  $\hat{\mathbf{k}} \times \hat{\mathbf{i}} = \hat{\mathbf{j}}$ 

(ii) Left handed system of vectors The vectors a, b and c mutually perpendicular to one another form a left handed system of vectors iff

$$\mathbf{c} \times \mathbf{b} = \mathbf{a}, \mathbf{a} \times \mathbf{c} = \mathbf{b}, \mathbf{b} \times \mathbf{a} = \mathbf{c}.$$

**Example 31.** The vectors  $\mathbf{c}, \mathbf{a} = x\mathbf{i} + y \mathbf{j} + z \mathbf{k}$  and  $b = \hat{j}$  are such that a,c and b form a right handed system, then c is

(a) 
$$z \hat{\mathbf{i}} - x \hat{\mathbf{k}}$$

(c) 
$$y \hat{j}$$

$$(d) - z\hat{\mathbf{i}} + x\hat{\mathbf{k}}$$

**Sol.** (a) **a**, **c** and **b** form a right handed system.

Hence, 
$$\mathbf{b} \times \mathbf{a} = \mathbf{c}$$
  

$$\Rightarrow \qquad \mathbf{c} = \hat{\mathbf{j}} \times (x \hat{\mathbf{i}} + y \hat{\mathbf{j}} + z \hat{\mathbf{k}})$$

$$= -x \hat{\mathbf{k}} + z \hat{\mathbf{i}} = z \hat{\mathbf{i}} - x \hat{\mathbf{k}}$$

**Example 32.** If **a**,**b** and **c** are three non-zero vectors such that  $\mathbf{a} \times \mathbf{b} = \mathbf{c}$  and  $\mathbf{b} \times \mathbf{c} = \mathbf{a}$ , prove that  $\mathbf{a}, \mathbf{b}$  and  $\mathbf{c}$ are mutually at right angles and  $|\dot{\mathbf{b}}| = 1$  and  $|\mathbf{c}| = |\mathbf{a}|$ .

**Sol.** 
$$\mathbf{a} \times \mathbf{b} = \mathbf{c}$$
 and  $\mathbf{a} = \mathbf{b} \times \mathbf{c}$ 

$$\Rightarrow$$
 c $\perp$ a, c $\perp$ b and a $\perp$ b, a $\perp$ c  $\Rightarrow$  a $\perp$ b, b $\perp$ c and c $\perp$ a

$$\Rightarrow$$
 **a**, **b** and **c** are mutually perpendicular vectors.

Again, 
$$\mathbf{a} \times \mathbf{b} = \mathbf{c}$$
 and  $\mathbf{b} \times \mathbf{c} = \mathbf{a}$ 

$$\Rightarrow$$
  $|\mathbf{a} \times \mathbf{b}| = |\mathbf{c}| \text{ and } |\mathbf{b} \times \mathbf{c}| = |\mathbf{a}|$ 

$$\Rightarrow |\mathbf{a}| |\mathbf{b}| \sin \frac{\pi}{2} = |\mathbf{c}| \text{ and } |\mathbf{b}| |\mathbf{c}| \sin \frac{\pi}{2} = |\mathbf{a}|$$

$$\Rightarrow$$
  $|\mathbf{a}| |\mathbf{b}| = |\mathbf{c}|$ 

and 
$$|\mathbf{b}| |\mathbf{c}| = |\mathbf{a}|$$
 (::  $\mathbf{a} \perp \mathbf{b}$  and  $\mathbf{b} \perp \mathbf{c}$ )

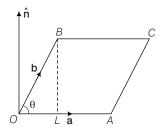

$$\Rightarrow$$
  $|\mathbf{b}|^2 |\mathbf{c}| = |\mathbf{c}|$ 

$$\Rightarrow$$
  $|\mathbf{b}|^2 = 1 \Rightarrow |\mathbf{b}| = 1$ 

On putting in 
$$|\mathbf{a}| |\mathbf{b}| = |\mathbf{c}| \Rightarrow |\mathbf{a}| = |\mathbf{c}|$$

### **Geometrical Interpretation** of Vector Product

If  $\mathbf{a}$  and  $\mathbf{b}$  are two non-zero, non-parallel vectors represented by **OA** and **OB** respectively and let  $\theta$  be the angle between them. Complete the parallelogram OACB. Draw  $BL \perp OA$ .

In 
$$\triangle OBL$$
,  $\sin \theta = \frac{BL}{OB}$   
 $\Rightarrow BL = OB \sin \theta = |\mathbf{b}| \sin \theta$   
Now,  $\mathbf{a} \times \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \sin \theta \mathbf{n}$   
 $= (OA) (BA) \mathbf{n}$ 

- = (Base  $\times$  Height)  $\mathbf{n}$  = (Area of parallelogram *OACB*)  $\mathbf{n}$
- = Vector area of the parallelogram OACB

Thus,  $\mathbf{a} \times \mathbf{b}$  is a vector whose magnitude is equal to the area of the parallelogram having  $\mathbf{a}$  and  $\mathbf{b}$  as its adjacent sides and whose direction  $\mathbf{n}$  is perpendicular to the plane of  $\mathbf{a}$  and  $\mathbf{b}$  such that  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{n}$  form a right handed system. Hence,  $\mathbf{a} \times \mathbf{b}$  represents the vector area of the parallelogram having adjacent sides along  $\mathbf{a}$  and  $\mathbf{b}$ .

# Area of Parallelogram and Triangle

- (i) The area of a parallelogram with adjacent sides  ${\bf a}$  and is  $|{\bf a}\times{\bf b}|$ .
- (ii) The area of a parallelogram with diagonals  ${\bf d}_1$  and  ${\bf d}_2$  is  $\frac{1}{2} | {\bf d}_1 \times {\bf d}_2 |$ .
- (iii) The area of a plane quadrilateral *ABCD* is  $\frac{1}{2} | \mathbf{AC} \times \mathbf{BD} |$ , where *AC* and *BD* are its diagonals.
- (iv) The area of a triangle with adjacent sides  $\mathbf{a}$  and  $\mathbf{b}$  is  $\frac{1}{2} | \mathbf{a} \times \mathbf{b} |$ .
- (v) The area of a  $\triangle ABC$  is  $\frac{1}{2} | \mathbf{AB} \times \mathbf{AC} |$ or  $\frac{1}{2} | \mathbf{BC} \times \mathbf{BA} |$ or  $\frac{1}{2} | \mathbf{CB} \times \mathbf{CA} |$
- (vi) If **a**, **b** and **c** are position vectors of a  $\triangle ABC$ , then its area =  $\frac{1}{2} | (\mathbf{a} \times \mathbf{b}) + (\mathbf{b} \times \mathbf{c}) + (\mathbf{c} \times \mathbf{a}) |$

### Domark

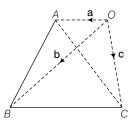

Three points with position vectors  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are collinear, if  $(\mathbf{a} \times \mathbf{b}) + (\mathbf{b} \times \mathbf{c}) + (\mathbf{c} \times \mathbf{a}) = 0$ 

**Example 33.** If  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are position vectors of the vertices A, B and C of  $\triangle ABC$ , show that the area of  $\triangle ABC$  is  $\frac{1}{2} |\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a}|$ .

Deduce the condition for points  $\mathbf{a}$ , $\mathbf{b}$  and  $\mathbf{c}$  to be collinear.

**Sol.** Area of 
$$\triangle ABC = \frac{1}{2} |\mathbf{AB} \times \mathbf{AC}|$$

Now,  $\mathbf{AB} = \text{Position vector of } B - \text{Position vector of } A$  $\mathbf{AB} = \mathbf{b} - \mathbf{a}$ 

 $\mathbf{AC}$  = Position vector of C – Position vector of A

$$AC = \mathbf{c} - \mathbf{a}$$

$$AB \times AC = (\mathbf{b} - \mathbf{a}) \times (\mathbf{c} - \mathbf{a})$$

$$= \mathbf{b} \times \mathbf{c} - \mathbf{b} \times \mathbf{a} - \mathbf{a} \times \mathbf{c} + \mathbf{a} \times \mathbf{a} \qquad (\because \mathbf{a} \times \mathbf{a} = 0)$$

$$= \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a}$$

Hence, area of  $\triangle ABC = \frac{1}{2} |\mathbf{AB} \times \mathbf{AC}|$ 

$$= \frac{1}{2} | \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} | = 0$$

If the points A, B and C are collinear, then area of  $\Delta ABC=0$ 

$$\Rightarrow \frac{1}{2} | \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} | = 0$$

$$\Rightarrow | \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} | = 0$$

$$\Rightarrow \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} = 0$$
Thus,
$$\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} = 0$$

is the required condition of collinearity of three points  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$ .

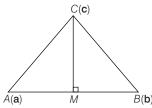

**Example 34.** Show that the perpendicular distance of the point **c** from to the joining **a** and **b** is

$$\frac{|\mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} + \mathbf{a} \times \mathbf{b}|}{|\mathbf{b} - \mathbf{a}|}$$

**Sol.** Let *ABC* be a triangle and let **a**, **b** and **c** be the position of its vertices *A*, *B* and *C* respectively. Let *CM* be the perpendicular from *C* on *AB*.

Then, area of 
$$\triangle ABC = \frac{1}{2}(AB) \cdot (CM) = \frac{1}{2} |\mathbf{AB}| |\mathbf{CM}|$$

Also, area of 
$$\triangle ABC = \frac{1}{2} | \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} |$$

$$\therefore \frac{1}{2} | \mathbf{AB} | | \mathbf{CM} | = \frac{1}{2} | \mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} |$$

$$\Rightarrow \qquad CM = \frac{|b \times c + c \times a + a \times b|}{|b - a|}$$

### Example 35.

(i) Find the area of the quadrilateral whose diagonals are given by

$$3\hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}}, \hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$$

(ii)  $A_1, A_2, ..., A_n$  are the vertices of a regular plane polygon with n sides. O is the centre. Show that

$$\sum_{i=1}^{n-1} (\mathbf{O} \mathbf{A}_i \times \mathbf{O} \mathbf{A}_{i+1}) = (1-n) (\mathbf{O} \mathbf{A}_2 \times \mathbf{O} \mathbf{A}_1)$$

**Sol.** (i) Area of the quadrilateral  $=\frac{1}{2}|d_1\times d_2|$ 

$$= \frac{1}{2} \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 3 & 1 & -2 \\ 1 & -3 & 4 \end{vmatrix} = \frac{1}{2} |-2\hat{\mathbf{i}} - 14\hat{\mathbf{j}} - 10\hat{\mathbf{k}}|$$

$$= \frac{1}{2}\sqrt{4 + 196 + 100} = \frac{10\sqrt{3}}{2} = 5\sqrt{3}$$

(ii)  $A_1, A_2, ..., A_n$  are the vertices of a regular plane polygon of n sides and centre O.

Let 
$$|\mathbf{OA}_i| = k, \forall i = 1 < 2, 3, ...., n$$

Let  $\hat{\mathbf{e}}_i$  be the unit vector along  $\mathbf{OA}_i$ 

$$\mathbf{O}\mathbf{A}_{i} = k\hat{\mathbf{e}}_{i}$$

$$\mathbf{O}\mathbf{A}_{i} \times \mathbf{O}\mathbf{A}_{i+1} = k\hat{\mathbf{e}}_{i} \times k\hat{\mathbf{e}}_{i+1} = k^{2}\hat{\mathbf{x}}_{i}$$

where  $\hat{\mathbf{x}}_i$  is a unit vector in the direction perpendicular to the plane of the polygon and  $\hat{\mathbf{x}}_i = \hat{\mathbf{x}}_{i+1}$  for

$$i = 1, 2, 3, \dots, n-1$$

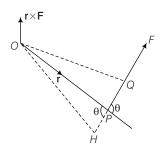

$$\therefore \qquad \text{LHS} = \sum_{i=1}^{n-1} (\mathbf{O}\mathbf{A}_i \times \mathbf{O}\mathbf{A}_{i+1}) = k^2 \sum_{r=1}^{n-1} \hat{\mathbf{x}}_i$$
$$= k^2 (n-1) \hat{\mathbf{x}}_i = (n-1) (\mathbf{O}\mathbf{A}_i \times \mathbf{O}\mathbf{A}_2)$$
$$= (1-n) (\mathbf{O}\mathbf{A}_2 \times \mathbf{O}\mathbf{A}_1)$$

# Moment of a Force and Couple

### Moment of a Force

(i) **About a point** Let a force **F** be applied at a point *P* of a rigid body then, the moment of **F** about a point O measures the tendency of F to turn the body about point O. If this tendency of rotation about O is in anti-clockwise direction, the moment is positive, otherwise it is negative.

Let **r** be the position vector of *P* relative to *O*. Then, the moment or torque of **F** about the point *O* is defined as the vector  $\mathbf{M} = \mathbf{r} \times \mathbf{F}$ .

If several forces are acting through the same point *P* then the vector sum of the moment of the separate forces about *O* is equal to the moment of their resultant force about O.

### Remark

Moment of a force **F** about a point  $\mathbf{A} = \mathbf{AB} \times \mathbf{F}$ , where **B** is any point on **F**.

(ii) About a line The moment of a force F acting at a point P about a line L is a scalar given by  $(\mathbf{r} \times \mathbf{F}) \cdot \hat{\mathbf{a}}$ , where **a** is a unit vector in the direction of the line and  $\mathbf{OP} = \mathbf{r}$ , where *O* is any point on the line.

Thus, the moment of a force F about a line is the resolved part (component) along this line, of the moment of F about any point on the line.

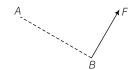

### Remark

The moment of a force about a point is a vector while the moment about a straight line is a scalar quantity.

**Example 36.** Find the moment about (1, -1, -1) of the force  $3\hat{i} + 4\hat{j} - 5\hat{k}$  acting at (1, 0, -2).

**Sol.** Let 
$$A \equiv (1, -1, -1), B \equiv (1, 0, -2)$$

and 
$$\mathbf{F} = 3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$$

Then, moment of force **F** about *A* is given by  $\mathbf{AB} \times \mathbf{F}$ .

Here, 
$$\mathbf{AB} = (\hat{\mathbf{i}} - 2\hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}} - \hat{\mathbf{k}}) = \hat{\mathbf{j}} - \hat{\mathbf{k}}$$

$$\mathbf{AB} \times \mathbf{F} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 0 & 1 & -1 \\ 3 & 4 & -5 \end{vmatrix}$$
$$= \hat{\mathbf{i}} (-5+4) - \hat{\mathbf{j}} (0+3) + \hat{\mathbf{k}} (0-3)$$
$$= -\hat{\mathbf{i}} - 3\hat{\mathbf{i}} - 3\hat{\mathbf{k}}$$

**Example 37.** Three forces  $\hat{i} + 2\hat{j} - 3\hat{k}$ ,  $2\hat{i} + 3\hat{j} + 4\hat{k}$ and  $\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}$  acting on a particle at the point (0, 1, 2). The magnitude of the moment of the forces about the point (1, -2, 0) is

(a) 
$$2\sqrt{35}$$

(b) 
$$6\sqrt{10}$$

(c) 
$$4\sqrt{7}$$

(d) None of these

**Sol.** (b) Total force 
$$\mathbf{F} = (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 3\hat{\mathbf{k}}) + (2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) + (\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) = 4\hat{\mathbf{i}} + 4\hat{\mathbf{i}} + 2\hat{\mathbf{k}}$$

Moment of the forces about

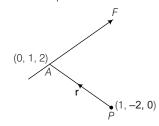

$$P = \mathbf{r} \times \mathbf{F} = \mathbf{P} \mathbf{A} \times \mathbf{F}$$

$$\mathbf{P} \mathbf{A} = (0 - 1)\hat{\mathbf{i}} + (1 + 2)\hat{\mathbf{j}} + (2 - 0)\hat{\mathbf{k}}$$

$$= -\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

 $\therefore$  Moment about  $P = (-\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) \times (4\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$ 

$$= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -1 & 3 & 2 \\ 4 & 4 & 2 \end{vmatrix} = -2\hat{\mathbf{i}} + 10\hat{\mathbf{j}} - 16\hat{\mathbf{k}}$$

Magnitude of the moment

$$= |-2\hat{\mathbf{i}} + 10\hat{\mathbf{j}} - 16\hat{\mathbf{k}}|$$
  
=  $2\sqrt{1^2 + 5^2 + 8^2} = 2\sqrt{90} = 6\sqrt{10}$ 

**Example 38.** Find the moment about a line through the origin having the direction of  $2\mathbf{i} - 2\mathbf{j} + \mathbf{k}$  due to 30 kg force acting at a point (-4, 2, 5) in the direction of 12i - 4j - 3k.

**Sol.** Let **F** be the force. Then

$$\mathbf{F} = \frac{30(12\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 3\hat{\mathbf{k}})}{\sqrt{144 + 16 + 9}} = \frac{30}{13}(12\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 3\hat{\mathbf{k}})$$

Suppose the force **F** acts at point P(-4, 2, 5) the moment of **F** acting at *P* about a line in the direction  $2\mathbf{i} - 2\mathbf{j} + \mathbf{k}$  is equal to the resolve part along the line of moment of F about a point on the line.

$$\therefore \quad \mathbf{r} = \mathbf{OP} = (-4\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 5\hat{\mathbf{k}}) - (0)$$
$$= -4\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$$

Let **M** be the moment **F** about *O*. Then,

$$\mathbf{M} = \mathbf{r} \times \mathbf{F} = \frac{30}{13} \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ -4 & 2 & 5 \\ 12 & -4 & -3 \end{vmatrix}$$

$$= \frac{30}{13} (4\hat{\mathbf{i}} + 48\hat{\mathbf{j}} - 8\hat{\mathbf{k}})$$

$$2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$$

$$(0, 0, 0)$$

$$r$$

$$P$$

Let **a** be unit vector in the direction of  $2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$ . Then,

$$\mathbf{a} = \frac{2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}}{\sqrt{4+4+1}} = \frac{1}{3}(2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}})$$

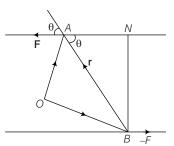

Thus, the moment of **F** about the given line

$$= \mathbf{M} \cdot \mathbf{a} = \frac{30}{13} \left( 14\hat{\mathbf{i}} + 48\hat{\mathbf{j}} - 8\hat{\mathbf{k}} \right)$$

$$\frac{1}{3}(2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}) = -\frac{760}{13}$$

## Moment of a Couple

A system consisting of a pair of equal unlike parallel forces is called a couple. The vector sum to two forces of a couple is always zero vector.

The moment of a couple is a vector perpendicular to the plane of couple and its magnitude is the product of the magnitude of either force with perpendicular distance between the lines of the forces.

$$\mathbf{M} = \mathbf{r} \times \mathbf{F}$$
, where  $\mathbf{r} = \mathbf{B}\mathbf{A}$ 

$$|\mathbf{M}| = |\mathbf{B}\mathbf{A} \times \mathbf{F}| = |\mathbf{F}| |\mathbf{B}\mathbf{A}| \sin \theta$$

where  $\theta$  is the angle between **BA** and **F** 

$$= |\mathbf{F}|(BN) = |\mathbf{F}|\alpha$$

where,  $\alpha = BN$  is the arm of the couple and + ve or - vesign is to be taken accordingly as the forces indicate a counter clockwise rotation or clockwise rotation.

**Example 39.** The moment of the couple formed by the forces  $5\mathbf{i} + \mathbf{k}$  and  $-5\mathbf{i} - \mathbf{k}$  acting at the points (9, -1, 2) and (3, -2, 1) respectively, is

(a) 
$$-\hat{\mathbf{i}} + \hat{\mathbf{i}} + 5\hat{\mathbf{k}}$$

c) 
$$2\hat{i} - 2\hat{i} - 10\hat{k}$$

(a) 
$$-\hat{\mathbf{i}} + \hat{\mathbf{j}} + 5\hat{\mathbf{k}}$$
 (b)  $\hat{\mathbf{i}} - \hat{\mathbf{j}} - 5\hat{\mathbf{k}}$  (c)  $2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 10\hat{\mathbf{k}}$  (d)  $-2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 10\hat{\mathbf{k}}$ 

**Sol.** (b) Moment of the couple,

$$(3, -2, 1)$$

$$-\mathbf{F} \bullet (-5\hat{\mathbf{i}} - \hat{\mathbf{k}})$$

$$= \mathbf{B}\mathbf{A} \times \mathbf{F} = \{(9 - 3) \,\hat{\mathbf{i}} + (-1 + 2) \,\hat{\mathbf{j}}$$

$$+ (2 - 1) \,\hat{\mathbf{k}}\} \times (5\hat{\mathbf{i}} + \hat{\mathbf{k}})$$

$$= (6\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) \times (5\hat{\mathbf{i}} + \hat{\mathbf{k}}) = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 6 & 1 & 1 \\ 5 & 0 & 1 \end{vmatrix}$$

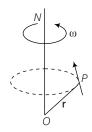

$$= \hat{\mathbf{i}} - \hat{\mathbf{j}} - 5\hat{\mathbf{k}}$$

## **Rotation About an Axis**

When a rigid body rotates about a fixed axis ON with an angular velocity  $\omega$ , then velocity  $\nu$  of a particle P is given by

$$v = \omega \times \mathbf{r},$$
 were,  $\mathbf{r} = \mathbf{OP}$ 

and  $\omega = |\omega|$  (unit vector along *ON*)

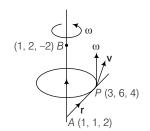

**Example 40.** A particle has an angular speed of 3 rad/s and the axis of rotation passes through the points (1, 1, 2) and (1, 2, -2). Find the velocity of the particle at point P(3, 6, 4).

**Sol.** Clearly, 
$$\mathbf{OA} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

$$\mathbf{OB} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$

$$\mathbf{AB} = \hat{\mathbf{j}} - 4\hat{\mathbf{k}} = |\mathbf{AB}| = \sqrt{17}$$

and 
$$\mathbf{AP} = (3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) - (\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$
$$= 2\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

$$\therefore \qquad \omega = \frac{3}{\sqrt{17}} (\hat{\mathbf{j}} - 4\hat{\mathbf{k}}) 2 \text{ and } \mathbf{r}$$
Now,  $\mathbf{v} = \omega \times \mathbf{r} = \frac{3}{\sqrt{17}} (\hat{\mathbf{j}} - 4\hat{\mathbf{k}}) \times (2\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$ 

$$= \frac{3}{\sqrt{17}} (22\hat{\mathbf{i}} - 8\hat{\mathbf{j}} - 2\hat{\mathbf{k}})$$

**Example 41.** A rigid body is spinning about a fixed point (3, -2, -1) with an angular velocity of 4 rad/s, the axis of rotation being in the direction of (1, 2, -2). Find the velocity of the particle at the point (4, 1, 1).

Sol. 
$$\omega = 4\left(\frac{\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}}}{\sqrt{1 + 4 + 4}}\right) = \frac{4}{3}(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}})$$

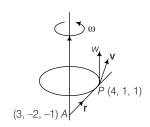

$$\mathbf{r} = \mathbf{OP} - \mathbf{OA}$$

$$= (4\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) - (3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - \hat{\mathbf{k}})$$

$$= \hat{\mathbf{i}} + 3\hat{\mathbf{i}} + 2\hat{\mathbf{k}}$$

$$\mathbf{v} = \omega \times \mathbf{r} = \frac{4}{3}(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}}) \times (\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

$$\Rightarrow \frac{4}{3}(10\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + \hat{\mathbf{k}})$$

# **Scalar Triple Product**

## **Scalar Triple Product**

The scalar triple product is defined for three vectors and it is defined as the dot product of one of the vectors with the cross product of the other two.

If  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$  are any three vector, then their scalar product is defined as  $(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}$ .

We denote it by [a, b, c].

It is also called the mixed or box product.

### Remark

Result of scalar triple product is always a scalar.

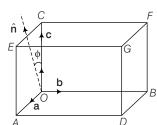

# Geometrical Interpretation of Scalar Triple Product

Let  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  be three vectors. Consider a parallelopiped having coterminous edges  $\mathbf{OA}$ ,  $\mathbf{OB}$  and  $\mathbf{OC}$  such that  $\mathbf{OA} = a$ ,  $\mathbf{OB} = b$  and  $\mathbf{OC} = c$ . Then,  $\mathbf{a} \times \mathbf{b}$  is a vector perpendicular to the plane of  $\mathbf{a}$  and  $\mathbf{b}$ . Let  $\phi$  be the angle between  $\mathbf{c}$  and  $\mathbf{a} \times \mathbf{b}$ .

If  $\, n \,$  is a unit vector along  $a \times b$ , then  $\varphi$  is the angle between  $\, n \,$  and  $\, c \,$ .

Now,

$$[\mathbf{a} \mathbf{b} \mathbf{c}] = (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}$$

- = (Area of parallelogram OADB)  $\mathbf{n} \cdot \mathbf{c}$
- = (Area of parallelogram OADB) ( $\mathbf{n} \cdot \mathbf{c}$ )
- = (Area of parallelogram OADB) ( $|c||n|\cos\phi$ )
- = (Area of parallelogram OADB) ( $|\mathbf{c}|\cos\phi$ )
- = (Area of parallelogram OADB) (OL)
- = Area of base  $\times$  height
- = Volume of parallelopiped

Height of parallelopiped

 $= \frac{\text{Volume of parallelopiped}}{\text{Area of base}}$ 

## **Properties of Scalar Triple Product**

(i) If  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are given by

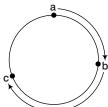

$$\mathbf{a} = a_1 \hat{\mathbf{i}} + a_2 \hat{\mathbf{j}} + a_3 \hat{\mathbf{k}}$$

$$\mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + b_3 \hat{\mathbf{k}}$$

$$\mathbf{c} = c_1 \hat{\mathbf{i}} + c_2 \hat{\mathbf{j}} + c_3 \hat{\mathbf{k}}$$

Then, 
$$(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} = \begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix}$$

- (ii)  $(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} = \mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})$  i.e. position of dot and cross can be interchanged without altering product. Hence, it is also represented by  $[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]$ .
- (iii) [a b c] = [b c a] = [c a b]
- (iv) [a b c] = -[b a c]
- (v)  $[k \mathbf{a} \mathbf{b} \mathbf{c}] = k[\mathbf{a} \mathbf{b} \mathbf{c}], [k_1 \mathbf{a} k_2 \mathbf{b} k_3 \mathbf{c}], = k_1 k_2 k_3 [\mathbf{a} \mathbf{b} \mathbf{c}]$
- (vi) [a + b c d] = [a c d] + [b c d]
- (vii)  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  in that order form a right handed system, if  $[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] > 0$ .

- (viii) The necessary and sufficient condition for three non-zero, non-collinear vector  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  to be coplanar is that  $[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = 0$  i.e.,  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are coplanar  $\Leftrightarrow [\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = 0$ .
- (ix)  $[x_1\mathbf{a} + y_1\mathbf{b} + z_1\mathbf{c}, x_2\mathbf{a} + y_2\mathbf{b} + z_2\mathbf{c}, x_3\mathbf{a} + y_3\mathbf{b} + z_3\mathbf{c}]$

$$= \begin{vmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ x_3 & y_3 & z_3 \end{vmatrix} [\mathbf{a} \, \mathbf{b} \, \mathbf{c}]$$

### Remarks

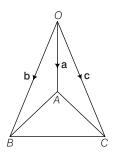

- **1.** Four points **A**, **B**, **C**, **D** are coplanar if [AB, AC, AD] = 0
- Four points a, b, c and d are coplanar, if
   [d b c] + [d c a] + [d a b] = [a b c]
   or
   [a b c] + [a c d] + [a d b] = [d b c]
- **3.**  $[\mathbf{a} \ \mathbf{a} \ \mathbf{b}] = [\mathbf{b} \ \mathbf{b} \ \mathbf{a}] = [\mathbf{c} \ \mathbf{c} \ \mathbf{b}] = 0$

i.e., if any two vectors are same, then vectors are coplanar.

# Volume of Tetrahedron (A pyramid having a triangular base)

If OABC is a tetrahedron as shown in figure, where OA = a, OB = b, and OC = c, then volume of

tetrahedron = 
$$\frac{1}{6}$$
[**a b c**]

### Remarks

- **1.** The six mid-points of the six edges of a tetrahedron lie in a sphere, if the pair of opposite edges are perpendicular to each other.
- 2. Centre of the sphere is the centroid of the tetrahedron.
- **3.**  $GA^2 + GB^2 + GC^2 + GO^2 = 12r^2$ , G being the centroid.
- **4.** The angle between any two plane faces of a regular tetrahedron is  $\cos^{-1}\frac{1}{3}$ .
- **5.** Angle between the any edge and a face not containing the angle is  $\cos^{-1}\sqrt{\frac{1}{3}}$  (for regular tetrahedron).
- **6.** Any two edges of regular tetrahedron are perpendicular to each other.
- 7. The distance of any vertex from the opposite face of regular tetrahedron is  $\sqrt{\frac{2}{3}}k$ , k being the length of any edge.
- **Example 42.** Find the volume of the parallelopiped whose edges are represented by  $\mathbf{a} = 2\hat{\mathbf{i}} 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$ ,  $\mathbf{b} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} \hat{\mathbf{k}}$  and  $\mathbf{c} = 3\hat{\mathbf{i}} \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ .

**Sol.** Here, 
$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = \begin{vmatrix} 2 & -3 & 4 \\ 1 & 2 & -1 \\ 3 & -1 & 2 \end{vmatrix} = 2(4-1) + 3(2+3) + 4(-1-6)$$
$$= 6 + 15 - 28 = -7$$

 $\therefore$  The volume of the parallelopiped =  $|[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]| = 7$ .

**Example 43.** Let  $\mathbf{a} = x\hat{\mathbf{i}} + 12\hat{\mathbf{j}} - \hat{\mathbf{k}}$ ,  $\mathbf{b} = 2\hat{\mathbf{i}} + 2x\hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\mathbf{c} = \hat{\mathbf{i}} + \hat{\mathbf{k}}$ . If  $\mathbf{b}, \mathbf{c}, \mathbf{a}$  in that order form a left handed system, then find the value of x.

$$[x_1\mathbf{a} + y_1\mathbf{b} + z_1\mathbf{c}, x_2\mathbf{a} + y_2\mathbf{b} + z_2\mathbf{c}, x_3\mathbf{a} + y_3\mathbf{b} + z_3\mathbf{c}]$$

$$= \begin{vmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ x_3 & y_3 & z_3 \end{vmatrix} [\mathbf{a} \mathbf{b} \mathbf{c}]$$

**Sol.** Since,  $\mathbf{b}$ ,  $\mathbf{c}$ ,  $\mathbf{a}$  form a left handed system, three fore  $[\mathbf{b}, \mathbf{c}, \mathbf{a}] < 0$ 

$$\begin{vmatrix} 2 & 2x & -1 \\ 1 & 0 & 1 \\ x & 12 & -1 \end{vmatrix} < 0$$

$$\Rightarrow 2(0 - 12) - 2x(-1 - x) + 1(12 - 0) < 0$$

$$\Rightarrow -24 + 2x + 2x^{2} + 12 < 0$$

$$\Rightarrow 2x^{2} + 2x - 12 < 0 \Rightarrow x^{2} + x - 6 < 0$$

$$\Rightarrow (x - 2)(x + 3) < 0 \Rightarrow x \in (-3, 2)$$

**Example 44.** For any three vectors  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  prove that  $[\mathbf{a} + \mathbf{b} \mathbf{b} + \mathbf{c} \mathbf{c} + \mathbf{a}] = 2[\mathbf{a} \mathbf{b} \mathbf{c}]$ 

Sol. We have, 
$$[\mathbf{a} + \mathbf{b} \ \mathbf{b} + \mathbf{c} \ \mathbf{c} + \mathbf{a}]$$
  

$$= \{(\mathbf{a} + \mathbf{b}) \times (\mathbf{b} \times \mathbf{c})\} \cdot (\mathbf{c} + \mathbf{a})$$

$$= \{\mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c} + \mathbf{b} \times \mathbf{b} + \mathbf{b} \times \mathbf{c}\} \cdot (\mathbf{c} + \mathbf{a})$$

$$= \{\mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c} + \mathbf{b} \times \mathbf{c}\} \cdot (\mathbf{c} + \mathbf{a})$$

$$= \{\mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c} + \mathbf{b} \times \mathbf{c}\} \cdot (\mathbf{c} + \mathbf{a})$$

$$= (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} + (\mathbf{a} \times \mathbf{c}) \cdot \mathbf{c} + (\mathbf{b} \times \mathbf{c}) \cdot \mathbf{c}$$

$$+ (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{a} + (\mathbf{a} \times \mathbf{c}) \cdot \mathbf{a} + (\mathbf{b} \times \mathbf{c}) \cdot \mathbf{a}$$

$$= [\mathbf{a} \ \mathbf{b} \ \mathbf{c}] + 0 + 0 + 0 + 0 + [\mathbf{b} \ \mathbf{c} \ \mathbf{a}]$$

$$[\because [\mathbf{a} \ \mathbf{c} \ \mathbf{c}] = 0, [\mathbf{b} \ \mathbf{c} \ \mathbf{c}] = 0,$$

$$[\mathbf{a} \ \mathbf{b} \ \mathbf{a}] = 0, [\mathbf{a} \ \mathbf{c} \ \mathbf{a}] = 0]$$

$$= [\mathbf{a} \ \mathbf{b} \ \mathbf{c}] + [\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = 2[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]$$

**Example 45.** If  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are coplanar show  $[\mathbf{a} + \mathbf{b} \mathbf{b} + \mathbf{c} \mathbf{c} + \mathbf{a}]$  are coplanar.

**Sol.** Since, [a b c] are coplanar

$$[\mathbf{a} \mathbf{b} \mathbf{c}] = 0 \qquad \dots (i)$$

and shown in above example

$$[\mathbf{a} + \mathbf{b} \ \mathbf{b} + \mathbf{c} \ \mathbf{c} + \mathbf{a}] = 2[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = 0$$
 [using Eq. (i)] which shows  $[\mathbf{a} + \mathbf{b} \ \mathbf{b} + \mathbf{c} \ \mathbf{c} + \mathbf{a}]$  are coplanar, if  $[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]$  are coplanar.

**Example 46.** For any three vectors **a**,**b** and **c** prove

that 
$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2 = \begin{vmatrix} \mathbf{a} \cdot \mathbf{a} & \mathbf{a} \cdot \mathbf{b} & \mathbf{a} \cdot \mathbf{c} \\ \mathbf{b} \cdot \mathbf{a} & \mathbf{b} \cdot \mathbf{b} & \mathbf{b} \cdot \mathbf{c} \\ \mathbf{c} \cdot \mathbf{a} & \mathbf{c} \cdot \mathbf{b} & \mathbf{c} \cdot \mathbf{c} \end{vmatrix}$$

On multiplying row-by-row, we get

$$[\mathbf{a} \mathbf{b} \mathbf{c}]^2 =$$

$$\begin{vmatrix} \mathbf{a}_{1}a_{1} + a_{2}a_{2} + a_{3}a_{3} & a_{1}b_{1} + a_{2}b_{2} + a_{3}b_{3} & a_{1}c_{1} + a_{2}c_{2} + a_{3}c_{3} \\ b_{1}a_{1} + b_{2}a_{2} + b_{3}a_{3} & b_{1}b_{1} + b_{2}b_{2} + b_{3}b_{3} & b_{1}c_{1} + b_{2}c_{2} + b_{3}c_{3} \\ c_{1}a_{1} + c_{2}a_{2} + c_{3}a_{3} & c_{1}b_{1} + c_{2}b_{2} + c_{3}b_{3} & c_{1}c_{1} + c_{2}c_{2} + c_{3}c_{3} \end{vmatrix}$$

$$= \begin{vmatrix} \mathbf{a} \cdot \mathbf{a} & \mathbf{a} \cdot \mathbf{b} & \mathbf{a} \cdot \mathbf{c} \\ \mathbf{b} \cdot \mathbf{a} & \mathbf{b} \cdot \mathbf{b} & \mathbf{b} \cdot \mathbf{c} \\ \mathbf{c} \cdot \mathbf{a} & \mathbf{c} \cdot \mathbf{b} & \mathbf{c} \cdot \mathbf{c} \end{vmatrix}$$

**Example 47.** If **a**, **b**, **c**, **l** and **m** are vectors, prove that

**Example 49.** If **a**,**b** and **c** are any three vectors in space, then show that

$$(c+b)\times(c+a)\cdot(c+b+a)=[a\ b\ c]$$

$$\Rightarrow (\mathbf{c} \times \mathbf{a} + \mathbf{b} \times \mathbf{c} + \mathbf{b} \times \mathbf{a}) \cdot (\mathbf{c} + \mathbf{b} + \mathbf{a}) \quad (\because \mathbf{c} \times \mathbf{c} = 0)$$

$$\Rightarrow (\mathbf{c} \times \mathbf{a}) \cdot \mathbf{c} + (\mathbf{c} \times \mathbf{a}) \cdot \mathbf{b} + (\mathbf{c} \times \mathbf{a}) \cdot \mathbf{a} + (\mathbf{b} \times \mathbf{c}) \cdot \mathbf{c} + (\mathbf{b} \times \mathbf{c}) \cdot \mathbf{b}$$

$$+ (\mathbf{b} \times \mathbf{c}) \cdot \mathbf{a} + (\mathbf{b} \times \mathbf{a}) \cdot \mathbf{c} + (\mathbf{b} \times \mathbf{a}) \cdot \mathbf{b} + (\mathbf{b} \times \mathbf{a}) \cdot \mathbf{a}$$

$$\Rightarrow 0 + [\mathbf{c} \mathbf{a} \mathbf{b}] + 0 + 0 + 0 + [\mathbf{b} \mathbf{c} \mathbf{a}] + [\mathbf{b} \mathbf{a} \mathbf{c}] + 0 + 0$$

$$\Rightarrow [\mathbf{a} \mathbf{b} \mathbf{c}] + [\mathbf{a} \mathbf{b} \mathbf{c}] - [\mathbf{a} \mathbf{b} \mathbf{c}]$$

$$\Rightarrow [\mathbf{a} \mathbf{b} \mathbf{c}] \quad (\because \mathbf{c} \mathbf{a} \mathbf{b} = \mathbf{a} \mathbf{b} \mathbf{c})$$

**Example 50.** If u, v and w are three non-coplanar vectors, then  $(u+v-w) \cdot [(u-v) \times (v-w)]$  is equal to

(a) 0 (b)  $\mathbf{u} \cdot (\mathbf{v} \times \mathbf{w})$  (c)  $\mathbf{u} \cdot (\mathbf{w} \times \mathbf{v})$  (d)  $3\mathbf{u} \cdot (\mathbf{v} \times \mathbf{w})$ 

**Example 51.** If a, b and c are non-coplanar vectors and  $\lambda$  is a real number, then the vector  $\mathbf{a} + 2\mathbf{b} + 3\mathbf{c}$ ,

 $\lambda$ **b** + 4**c** and  $(2\lambda - 1)$ **c** are non-coplanar for

- (a) no value of  $\lambda$
- (b) all except one value of  $\lambda$
- (c) all except two values of  $\lambda$
- (d) all values of  $\lambda$

**Sol.** (c) Since, **a**, **b** and **c** are non-coplanar vectors.

$$(\mathbf{a} \mathbf{b} \mathbf{c}) \neq 0$$

Now,  $\mathbf{a} + 2\mathbf{b} + 3\mathbf{c}$ ,  $\lambda \mathbf{b} + 4\mathbf{c}$  and  $(2\lambda - 1)\mathbf{c}$  will be non-coplanare iff

$$(\mathbf{a} + 2\mathbf{b} + 3\mathbf{c}) \cdot \{(\lambda \mathbf{b} + 4\mathbf{c}) \times (2\lambda - 1) \mathbf{c}\} \neq 0$$
i.e., 
$$(\mathbf{a} + 2\mathbf{b} + 3\mathbf{c}) \cdot \{\lambda(2\lambda - 1) (\mathbf{b} \times \mathbf{c}) \neq 0$$
i.e., 
$$\lambda(2\lambda - 1) [\mathbf{a} \mathbf{b} \mathbf{c}]\} \neq 0$$

$$\therefore \qquad \lambda \neq 0, \frac{1}{2}$$

Thus, given vectors will be non-coplanar for all values of  $\lambda$  except two values 0 and  $\frac{1}{2}$ .

**Example 52.** If x, y and z are distinct scalars such that  $[x\mathbf{a} + y\mathbf{b} + z\mathbf{c}, x\mathbf{b} + y\mathbf{c} + z\mathbf{a}, x\mathbf{c} + y\mathbf{a} + z\mathbf{b}] = 0]$  where  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  are non-coplanar vectors, then

(a) 
$$x + y + z = 0$$

$$(b) xy + yz + zx = 0$$

(c) 
$$x^3 + v^3 + z^3 = 0$$

(d) 
$$x^2 + v^2 + z^2 = 0$$

**Sol.** (a) **a**, **b** and **c** are non-coplanar.

$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \neq 0$$

Now, consider 
$$[x\mathbf{a} + y\mathbf{b} + z\mathbf{c}, x\mathbf{b} + y\mathbf{c} + z\mathbf{a}, x\mathbf{c} + y\mathbf{a} + z\mathbf{b}] = 0$$

$$\Rightarrow \begin{vmatrix} x & y & z \\ z & x & y \\ y & z & x \end{vmatrix} [\mathbf{a} \mathbf{b} \mathbf{c}] = 0 \Rightarrow \begin{vmatrix} x & y & z \\ z & x & y \\ y & z & x \end{vmatrix} = 0 \quad [\because [\mathbf{a} \mathbf{b} \mathbf{c}] \neq 0]$$

$$\Rightarrow (x + y + z)(x^{2} + y^{2} + z^{2} - xy - yz - zx) = 0$$

$$\Rightarrow \frac{1}{2}(x+y+z)\{(x-y)^2\}+(y-z)^2+(z-x)^2\}=0$$

$$\Rightarrow$$
  $x + y + z = 0$  or  $x = y = z$ 

But x, y and z are distinct

$$\therefore \qquad x + y + z = 0.$$

# **Session 4**

# **Vector Triple Product**

## **Vector Triple Product**

It is defined for three vectors **a**, **b** and **c** as the vector  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c})$ .

This vector being perpendicular to **a** and  $\mathbf{b} \times \mathbf{c}$ . But  $\mathbf{b} \times \mathbf{c}$  is a vector perpendicular to the plane of **b** and **c**.

 $\therefore$  **a**  $\times$  (**b**  $\times$  **c**) lie in the plane of **b** and **c**, i.e., it is coplanar with **b** and **c**.

i.e., 
$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = l\mathbf{b} + m\mathbf{c}$$
 ...(i)

Taking the scalar product of this equation with a, we get

$$0 = l(\mathbf{a} \cdot \mathbf{b}) + m(\mathbf{a} \cdot \mathbf{c}) \qquad \left[ \begin{array}{c} \because \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) \text{ is } \bot \text{ to } \mathbf{a} \\ \therefore (\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) \cdot \mathbf{a} = 0 \end{array} \right]$$

$$\Rightarrow \qquad l(\mathbf{a} \cdot \mathbf{b}) = -m(\mathbf{a} \cdot \mathbf{c})$$

$$\Rightarrow \qquad \frac{l}{\mathbf{a} \cdot \mathbf{c}} = -\frac{m}{\mathbf{a} \cdot \mathbf{b}} = \lambda \qquad \text{(say)}$$

$$\Rightarrow \qquad l = \lambda(\mathbf{a} \cdot \mathbf{c})$$
and
$$m = -\lambda(\mathbf{a} \cdot \mathbf{b})$$

Substituting the value of l and m in Eq. (i), we get

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \lambda [(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}]$$

Here, the value of  $\lambda$  can be determined by taking specific values of a, b and c.

If we choose the coordinate axes in such a way that,

$$\mathbf{a} = a_1 \hat{\mathbf{i}}, \mathbf{b} = b_1 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}}$$
  
and 
$$\mathbf{c} = c_1 \hat{\mathbf{i}} + c_2 \hat{\mathbf{j}} + c_3 \hat{\mathbf{k}},$$

it is easy to show that  $\lambda = 1$ .

Hence, 
$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c})=(\mathbf{a}\cdot\mathbf{c})\;\mathbf{b}-(\mathbf{a}\cdot\mathbf{b})\,\mathbf{c}$$
 and 
$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c})=(\mathbf{a}\times\mathbf{b})\times\mathbf{c}, \text{ if some of all } \mathbf{a}, \mathbf{b} \text{ and } \mathbf{c} \text{ are zero vectors or } \mathbf{a} \text{ and } \mathbf{c} \text{ are collinear.}$$

### Remarks

- **1.**  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c})$  is a linear combination of those two vectors which are with in brackets.
- 2. If  $\mathbf{r} = \mathbf{a} \times (\mathbf{b} \times \mathbf{c})$ , then  $\mathbf{r}$  is perpendicular to  $\mathbf{a}$  and lie in the plane of **b** and **c**.
- 3.  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \cdot \mathbf{c}) \mathbf{b} (\mathbf{a} \cdot \mathbf{b}) \mathbf{c}$  $(\mathbf{a} \times \mathbf{b}) \times \mathbf{c} = (\mathbf{c} \cdot \mathbf{a}) \mathbf{b} - (\mathbf{c} \cdot \mathbf{b}) \mathbf{a}$ Aid to memory

 $|\times (|\times||) = (|\cdot||) ||- (|\cdot||) ||$ 

4. 
$$(\mathbf{a} \times \mathbf{b}) \times (\mathbf{c} \times \mathbf{d}) = ((\mathbf{a} \times \mathbf{b}) \cdot \mathbf{d}) \mathbf{c} - ((\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}) \mathbf{d}$$
  
=  $[\mathbf{a} \mathbf{b} \mathbf{d}] \mathbf{c} - [\mathbf{a} \mathbf{b} \mathbf{c}] \mathbf{d}$ 

 $\Rightarrow$  The vector  $(\mathbf{a} \times \mathbf{b}) \times (\mathbf{c} \times \mathbf{d})$  lies in the plane of  $\mathbf{c}$  and  $\mathbf{d}$ .

Also, 
$$(\mathbf{a} \times \mathbf{b}) \times (\mathbf{c} \times \mathbf{d}) = -(\mathbf{c} \times \mathbf{d}) \times (\mathbf{a} \times \mathbf{b})$$
  
=  $-\{((\mathbf{c} \times \mathbf{d}) \cdot \mathbf{b}) \mathbf{a} - ((\mathbf{c} \times \mathbf{d}) \cdot (\mathbf{a} \mathbf{b})\}$   
=  $-[\mathbf{c} \mathbf{d} \mathbf{b}] \mathbf{a} + [\mathbf{c} \mathbf{d} \mathbf{a}] \mathbf{b}$ 

Which shows that  $(\mathbf{a} \times \mathbf{b}) \times (\mathbf{c} \times \mathbf{d})$  lies in the plane of  $\mathbf{a}$  and  $\mathbf{b}$ . Thus, the vector  $(\mathbf{a} \times \mathbf{b}) \times (\mathbf{c} \times \mathbf{d})$  lies along the common section of the plane of c,d and that of the plane of a, b.

Lagrange's Identity 
$$(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{c} \times \mathbf{d}) = \begin{vmatrix} \mathbf{a} \cdot \mathbf{c} & \mathbf{a} \cdot \mathbf{d} \\ \mathbf{b} \cdot \mathbf{c} & \mathbf{b} \cdot \mathbf{d} \end{vmatrix}$$

Proof
$$LHS = (\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{c} \times \mathbf{d}) = \mathbf{u} \cdot (\mathbf{c} \times \mathbf{d})$$
where
$$\mathbf{u} = \mathbf{a} \times \mathbf{b} = (\mathbf{u} \times \mathbf{c}) \cdot \mathbf{d}$$

$$= ((\mathbf{a} \times \mathbf{b}) \times \mathbf{c}) \cdot \mathbf{d}$$

$$= ((\mathbf{c} \cdot \mathbf{a}) \cdot \mathbf{b} - (\mathbf{c} \cdot \mathbf{a}) \cdot \mathbf{a}) \cdot \mathbf{d}$$

$$= (\mathbf{c} \cdot \mathbf{a}) (\mathbf{b} \cdot \mathbf{d}) - (\mathbf{c} \cdot \mathbf{b}) (\mathbf{a} \cdot \mathbf{d})$$

$$= (\mathbf{a} \cdot \mathbf{c}) (\mathbf{b} \cdot \mathbf{d}) - (\mathbf{b} \cdot \mathbf{c}) (\mathbf{a} \cdot \mathbf{d})$$

$$= \begin{vmatrix} \mathbf{a} \cdot \mathbf{c} & \mathbf{a} \cdot \mathbf{d} \\ \mathbf{b} & \mathbf{a} & \mathbf{b} & \mathbf{d} \end{vmatrix}$$

**Example 54.** If  $\mathbf{a} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}, \mathbf{b} = \hat{\mathbf{i}} + \hat{\mathbf{j}}, \mathbf{c} = \hat{\mathbf{i}}$  and  $(\mathbf{a} \times \mathbf{b}) \times \mathbf{c} = \lambda \mathbf{a} + \mu \mathbf{b}$ , then  $\lambda + \mu$  is equal to

Sol. (a) 
$$(\mathbf{a} \times \mathbf{b}) \times \mathbf{c} = \lambda \mathbf{a} + \mu \mathbf{b}$$
  

$$\Rightarrow (\mathbf{a} \cdot \mathbf{c}) \mathbf{b} - (\mathbf{b} \cdot \mathbf{c}) \mathbf{a} = \lambda \mathbf{a} + \mu \mathbf{b}$$

$$\Rightarrow \lambda = -\mathbf{b} \cdot \mathbf{c}, \mu = \mathbf{a} \cdot \mathbf{c}$$

$$\therefore \lambda + \mu = \mathbf{a} \cdot \mathbf{c} - \mathbf{b} \cdot \mathbf{c} = (\mathbf{a} - \mathbf{b}) \cdot \mathbf{c}$$

$$= \{(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) - (\hat{\mathbf{i}} + \hat{\mathbf{j}})\} = \hat{\mathbf{k}} \cdot \hat{\mathbf{i}} = 0$$

**Example 55.** If **a** ,**b** and **c** are three non-parallel unit vectors such that  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \frac{1}{2}\mathbf{b}$ , then find the angles which  $\mathbf{a}$  makes with  $\mathbf{b}$  and  $\mathbf{c}$ .

**Sol.** We have, 
$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \frac{1}{2}\mathbf{b}$$

$$\Rightarrow (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c} = \frac{1}{2}\mathbf{b}$$

$$\Rightarrow \mathbf{a} \cdot \mathbf{c} = \frac{1}{2} \text{ and } \mathbf{a} \cdot \mathbf{b} = 0 \qquad \text{(comparing } \mathbf{c} \text{ and } \mathbf{b}\text{)}$$

$$\Rightarrow \mathbf{a} \cdot \mathbf{c} = \frac{1}{2} \text{ and } \mathbf{a} \perp \mathbf{b}$$

Suppose **a** makes angle  $\theta$  with **c**. Then,  $\mathbf{a} \cdot \mathbf{c} = \frac{1}{2}$ 

$$\Rightarrow |\mathbf{a}| |\mathbf{c}| \cos \theta = \frac{1}{2} \Rightarrow \cos \theta = \frac{1}{2} \qquad (: |\mathbf{a}| |\mathbf{c}| \neq 0)$$

$$\Rightarrow \theta = \frac{\pi}{3}$$

Thus, **a** is perpendicular to **b** and makes an angle  $\frac{\pi}{3}$  with **c**.

- **Example 56.** If  $\mathbf{a} = -\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\mathbf{b} = 2\hat{\mathbf{i}} + \hat{\mathbf{k}}$ , then find the vector *x* satisfying the conditions.
  - (i) that it is coplanar with **a** and **b**.
  - (ii) it is perpendicular to **b**.
  - (iii)  $\mathbf{a} \cdot \mathbf{x} = 7$

**Sol.** Since, x is in the plane of  $\mathbf{a}$  and  $\mathbf{b}$  and is perpendicular to  $\mathbf{b}$ .

$$\therefore x = \lambda \{\mathbf{b} \times (\mathbf{a} \times \mathbf{b})\}$$

$$\Rightarrow x = \lambda \{(\mathbf{b} \cdot \mathbf{b}) \mathbf{a} - (\mathbf{b} \cdot \mathbf{a}) \mathbf{b}\}$$

$$= \lambda \{5(-\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) - (-1)(2\hat{\mathbf{i}} + \hat{\mathbf{k}})\}$$

$$= \lambda \{-5\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 5\hat{\mathbf{k}} + 2\hat{\mathbf{i}} + \hat{\mathbf{k}}\}$$

$$= \lambda \{-3\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 6\hat{\mathbf{k}}\}$$

Now,  $\mathbf{a} \cdot \mathbf{x} = 7$ 

$$\Rightarrow \qquad -3\lambda + 5\lambda + 6\lambda = 7$$

$$\Rightarrow \qquad 8\lambda = 7 \Rightarrow \lambda = \frac{7}{8}$$

Hence, 
$$x = \frac{7}{8} (-3\hat{\mathbf{i}} + 5\hat{\mathbf{j}} + 6\hat{\mathbf{k}})$$

**Example 57.** Prove that

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) + \mathbf{b} \times (\mathbf{c} \times \mathbf{a}) + \mathbf{c} \times (\mathbf{a} \times \mathbf{b}) = 0$$

Sol. We have, 
$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) + \mathbf{b} \times (\mathbf{c} \times \mathbf{a}) + \mathbf{c} \times (\mathbf{a} \times \mathbf{b}) = 0$$

$$= \{(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}\} + \{(\mathbf{b} \cdot \mathbf{a})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a}\} + \{(\mathbf{c} \cdot \mathbf{b})\mathbf{a} - (\mathbf{c} \cdot \mathbf{a})\mathbf{b}\}$$

$$= [(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c} + (\mathbf{a} \cdot \mathbf{b})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a} + (\mathbf{b} \cdot \mathbf{c})\mathbf{a} - (\mathbf{a} \cdot \mathbf{c})\mathbf{b}] = 0$$

### **Example 58.** Show that the vectors

 $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}), \mathbf{b} \times (\mathbf{c} \times \mathbf{a})$  and  $\mathbf{c} \times ((\mathbf{a} \times \mathbf{b}))$  are coplanar.

**Sol.** Let 
$$\mathbf{p} = \mathbf{a} \times (\mathbf{b} \times \mathbf{c})$$
,  $\mathbf{q} = \mathbf{b} \times (\mathbf{c} \times \mathbf{a})$  and  $\mathbf{r} = \mathbf{c} \times (\mathbf{a} \times \mathbf{b})$ , then  $\mathbf{p} + \mathbf{q} + \mathbf{r} = \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) + \mathbf{b} \times (\mathbf{c} \times \mathbf{a}) + \mathbf{c} \times (\mathbf{a} \times \mathbf{b}) = 0$   $\Rightarrow \mathbf{p} = (-1), \mathbf{q} = (-1) \mathbf{r}$  which shows  $\mathbf{p}$  is linear combination of  $\mathbf{q}$  and  $\mathbf{r}$ . So,  $\mathbf{p}$ ,  $\mathbf{q}$  are coplanar. Hence,  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c})$ ,  $\mathbf{b} \times (\mathbf{c} \times \mathbf{a})$  and  $\mathbf{c} \times (\mathbf{a} \times \mathbf{b})$  are coplanar.

Sol. We have, 
$$[\mathbf{a} \times \mathbf{b} \ \mathbf{b} \times \mathbf{c} \ \mathbf{c} \times \mathbf{a}]$$
  

$$= \{(\mathbf{a} \times \mathbf{b}) \times (\mathbf{b} \times \mathbf{c})\} \cdot (\mathbf{c} \times \mathbf{a})$$

$$= \{\mathbf{d} \times (\mathbf{b} \times \mathbf{c})\} \cdot (\mathbf{c} \times \mathbf{a}) \quad [\text{where, } \mathbf{d} = (\mathbf{a} \times \mathbf{b})]$$

$$= [(\mathbf{d} \cdot \mathbf{c})\mathbf{b} - (\mathbf{d} \cdot \mathbf{b})\mathbf{c}] \cdot (\mathbf{c} \times \mathbf{a})$$

$$= [\{(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c}\} \mathbf{b} - (\mathbf{a} \times \mathbf{b}) \mathbf{b}\} \mathbf{c}] \cdot (\mathbf{c} \times \mathbf{a})$$

$$= \{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \ \mathbf{b} - 0\} \cdot (\mathbf{c} \times \mathbf{a}) \quad [\because (\mathbf{a} \ \mathbf{b} \ \mathbf{b}) = 0]$$

$$= \{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \ \{\mathbf{b} \cdot (\mathbf{c} \times \mathbf{a})\}$$

$$= [\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \ [\mathbf{b} \ \mathbf{c} \ \mathbf{a}]$$

**Example 60.** If **a**, **b** and **c** are coplanar show  $[\mathbf{a} \times \mathbf{b} \mathbf{b} \times \mathbf{c} \mathbf{c} \times \mathbf{a}]$  are coplanar.

**Sol.** Since, [a b c] are coplanar.

and  $[\mathbf{a} \times \mathbf{b} \ \mathbf{b} \times \mathbf{c} \ \mathbf{c} \times \mathbf{a}] = [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2 = 0$

 $\therefore$  [**a**  $\times$  **b b**  $\times$  **c c**  $\times$  **a**] are coplanar, if **a**, **b** and **c** are

**Example 61.** If A, B and C are vectors such that

 0 = RHS

### **Example 62.** If b and c are two non-collinear vector such that a $||(b \times c)|$ , then prove that

$$(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{a} \times \mathbf{c})$$
 is equal to  $|\mathbf{a}|^2$  (b·c).

**Sol.** Since, 
$$\mathbf{a} \parallel (\mathbf{b} \times \mathbf{c})$$
, therefore  $\mathbf{a} \perp \mathbf{b}$  and  $\mathbf{a} \perp \mathbf{c}$ 

$$\Rightarrow \mathbf{a} \cdot \mathbf{b} = 0 \text{ and } \mathbf{a} \cdot \mathbf{c} = 0$$
Now, consider  $(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{a} \times \mathbf{c}) = \begin{vmatrix} \mathbf{a} \cdot \mathbf{a} & \mathbf{a} \cdot \mathbf{c} \\ \mathbf{b} \cdot \mathbf{a} & \mathbf{b} \cdot \mathbf{c} \end{vmatrix} = \begin{vmatrix} \mathbf{a} \cdot \mathbf{a} & 0 \\ 0 & \mathbf{b} \cdot \mathbf{c} \end{vmatrix}$ 

 $= (\mathbf{a} \cdot \mathbf{a}) (\mathbf{b} \cdot \mathbf{c}) = |\mathbf{a}^2| (\mathbf{b} \cdot \mathbf{c}).$ 

## Reciprocal System of Vectors

The two system of vectors are called reciprocal system of vectors if by taking dot product, we get unity.

Thus, if **a**, **b** and **c** be three non-coplanar vectors and if.

$$\mathbf{a'} = \frac{\mathbf{b} \times \mathbf{c}}{|\mathbf{a} \mathbf{b} \mathbf{c}|}, \mathbf{b'} = \frac{\mathbf{c} \times \mathbf{a}}{|\mathbf{a} \mathbf{b} \mathbf{c}|} \text{ and } \mathbf{c'} = \frac{\mathbf{a} \times \mathbf{b}}{|\mathbf{a} \mathbf{b} \mathbf{c}|}$$

Then a', b' and c' are said to be reciprocal system of vectors for the vector **a**, **b** and **c**.

### Remarks

1. If 
$$\mathbf{a}$$
,  $\mathbf{b}$ ,  $\mathbf{c}$  and  $\mathbf{a'}$ ,  $\mathbf{b'}$ ,  $\mathbf{c'}$  are reciprocal system of vectors, then 
$$\mathbf{a} \cdot \mathbf{a'} = \frac{\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})}{(\mathbf{a} \ \mathbf{b} \ \mathbf{c})} = \frac{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} = 1$$

$$\mathbf{a} \cdot \mathbf{a'} = \frac{\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})}{(\mathbf{a} \ \mathbf{b} \ \mathbf{c})} = \frac{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} =$$

Similarly,  $\mathbf{b} \cdot \mathbf{b'} = \mathbf{c} \cdot \mathbf{c'} = 1$ 

2. 
$$\mathbf{a} \cdot \mathbf{b'} = \mathbf{a} \cdot \mathbf{c'} = \mathbf{b} \cdot \mathbf{a'} = \mathbf{b} \cdot \mathbf{a'} = \mathbf{c} \cdot \mathbf{a'} = \mathbf{c} \cdot \mathbf{b'} = 0$$

**3.** 
$$[a b c] \cdot [a' b' c'] = 1$$

Proof: We have.

$$[\mathbf{a}' \, \mathbf{b}' \, \mathbf{c}'] = \left[ \frac{\mathbf{b} \times \mathbf{c}}{[\mathbf{a} \, \mathbf{b} \, \mathbf{c}]} = \frac{\mathbf{c} \times \mathbf{a}}{[\mathbf{a} \, \mathbf{b} \, \mathbf{c}]} = \frac{\mathbf{a} \times \mathbf{b}}{[\mathbf{a} \, \mathbf{b} \, \mathbf{c}]} \right]$$

$$= \frac{1}{[\mathbf{a} \, \mathbf{b} \, \mathbf{c}]^3} [\mathbf{b} \times \mathbf{c} \, \mathbf{c} \times \mathbf{a} \, \mathbf{a} \times \mathbf{b}] = \frac{1}{[\mathbf{a} \, \mathbf{b} \, \mathbf{c}]^3} [\mathbf{a} \, \mathbf{b} \, \mathbf{c}]^2$$

$$= \frac{1}{[\mathbf{a} \, \mathbf{b} \, \mathbf{c}]}$$

$$\therefore [\mathbf{a}' \mathbf{b}' \mathbf{c}'] \cdot [\mathbf{a} \mathbf{b} \mathbf{c}] = 1$$

### **4.** The orthogonal triad of vectors $\hat{\mathbf{i}}$ , $\hat{\mathbf{j}}$ and $\hat{\mathbf{k}}$ is self reciprocal.

Let  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$  be the system of vectors reciprocal to the system  $\hat{i}$ ,  $\hat{i}$  and  $\hat{k}$  then, we have,

$$\hat{\mathbf{i}} = \frac{\hat{\mathbf{j}} \times \hat{\mathbf{k}}}{\left[\hat{\mathbf{i}} \ \hat{\mathbf{j}} \ \hat{\mathbf{k}}\right]} = \hat{\mathbf{j}}$$

Similarly. 
$$\hat{\mathbf{i}}' = \hat{\mathbf{i}}$$
 and  $\hat{\mathbf{k}}' =$ 

5. a, b and c are non-coplanar iff a', b', c' are non-coplanar.

$$\therefore \qquad [\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \ [\mathbf{a'} \ \mathbf{b'} \ \mathbf{c'}] = 1$$

$$\therefore \qquad [\mathbf{a'} \ \mathbf{b'} \ \mathbf{c'}] = \frac{1}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}$$

So, 
$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \neq 0 \Leftrightarrow [\mathbf{a}' \ \mathbf{b}' \ \mathbf{c}'] \neq 0$$

Thus, **a**, **b** and **c** are non-coplanar iff [**a**'**b**'**c**'] are non-coplanar.

6. If a, b, c are non-coplanar vectors, then

$$\mathbf{r} = \frac{[\mathbf{x} \, \mathbf{b} \, \mathbf{c}] \, \mathbf{a} \, + [\mathbf{x} \, \mathbf{c} \, \mathbf{a}] \, \mathbf{b} + [\mathbf{x} \, \mathbf{a} \, \mathbf{b}] \, \mathbf{c}}{[\mathbf{a} \, \mathbf{b} \, \mathbf{c}]}$$

### Example 63. Find the set of vectors reciprocal to the set of vectors $2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - \hat{\mathbf{k}}$ , $\hat{\mathbf{i}} - \hat{\mathbf{j}} - 2\hat{\mathbf{k}}$ , $-\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$

**Sol.** Let the given vector be **a**, **b**, **c**.

Now, 
$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = \begin{vmatrix} 2 & 3 & -1 \\ 1 & -1 & -2 \\ -1 & 2 & 2 \end{vmatrix}$$

$$= 2(-2+4) - 3(2-2) - 1(2-1)$$

$$= 4-1=3$$

$$\mathbf{b} \times \mathbf{c} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & -1 & -2 \\ -1 & 2 & 2 \end{vmatrix} = 2\hat{\mathbf{i}} + \hat{\mathbf{k}}$$

$$\mathbf{c} \times \mathbf{a} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & -1 & -2 \\ 2 & 3 & -1 \end{vmatrix} = -8\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 7\hat{\mathbf{k}}$$

$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & 3 & -1 \\ 1 & -1 & -2 \end{vmatrix} = -7\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$$
Hence,
$$\mathbf{a}' = \frac{\mathbf{b} \times \mathbf{c}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} = \frac{2\hat{\mathbf{i}} + \hat{\mathbf{k}}}{3}$$

$$\mathbf{b}' = \frac{\mathbf{c} \times \mathbf{a}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} = \frac{-8\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 7\hat{\mathbf{k}}}{3}$$
and
$$\mathbf{c}' = \frac{\mathbf{a} \times \mathbf{b}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} = \frac{-7\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 5\hat{\mathbf{k}}}{3}$$

### **Example 64.** Find a set of vector reciprocal to the vectors $\mathbf{a}, \mathbf{b}$ and $\mathbf{a} \times \mathbf{b}$ .

**Sol.** Let the given vectors be denoted by  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{c}$  where  $c = a \times b$ .

$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} = (\mathbf{a} \times \mathbf{b}) = (\mathbf{a} \times \mathbf{b})^2 \quad \dots (i)$$

and let the reciprocal system of vector be a', b' and c'.

$$\therefore \quad \mathbf{a'} = \frac{\mathbf{b} \times \mathbf{c}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} = \frac{\mathbf{b} \times (\mathbf{a} \times \mathbf{b})}{[\mathbf{a} \times \mathbf{b}]^2}$$
$$\mathbf{b'} = \frac{\mathbf{c} \times \mathbf{a}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} = \frac{(\mathbf{a} \times \mathbf{b}) \times \mathbf{a}}{[\mathbf{a} \times \mathbf{b}]^2}$$
$$\mathbf{c'} = \frac{\mathbf{a} \times \mathbf{b}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} = \frac{\mathbf{a} \times \mathbf{b}}{[\mathbf{a} \times \mathbf{b}]^2}$$

∴ a', b' and c' are required reciprocal system of vectors for  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{a} \times \mathbf{b}$ .

# **Example 65.** If $\mathbf{a}' = \frac{\mathbf{b} \times \mathbf{c}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}$ , $\mathbf{b}' = \frac{\mathbf{c} \times \mathbf{a}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}$ , $\mathbf{c}' = \frac{\mathbf{a} \times \mathbf{b}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}$

then show that

 $\mathbf{a} \times \mathbf{a'} + \mathbf{b} \times \mathbf{b'} + \mathbf{c} \times \mathbf{c'} = 0$ , where  $\mathbf{a}, \mathbf{b}$  and  $\mathbf{c}$  are non-coplanar.

Sol. Here, 
$$\mathbf{a} \times \mathbf{a'} = \frac{\mathbf{a} \times (\mathbf{b} \times \mathbf{c})}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}$$

$$\mathbf{a} \times \mathbf{a'} = \frac{(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b}) \mathbf{c}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} \qquad ...(i)$$

Similarly,

$$\mathbf{b} \times \mathbf{b'} = \frac{(\mathbf{b} \cdot \mathbf{a}) \mathbf{c} - (\mathbf{b} \cdot \mathbf{c}) \mathbf{a}}{[\mathbf{a} \mathbf{b} \mathbf{c}]}$$
 ...(ii)

$$\mathbf{c} \times \mathbf{c}' = \frac{(\mathbf{c} \cdot \mathbf{b})\mathbf{a} - (\mathbf{c} \cdot \mathbf{a}) \mathbf{b}}{[\mathbf{a} \mathbf{b} \mathbf{c}]}$$
 ...(iii)

$$\begin{aligned} \mathbf{a} \times \mathbf{a}' + \mathbf{b} \times \mathbf{b}' + \mathbf{c} \times \mathbf{c}' \\ & (\mathbf{a} \cdot \mathbf{c}) \mathbf{b} - (\mathbf{a} \cdot \mathbf{b}) \mathbf{c} + (\mathbf{b} \cdot \mathbf{a}) \mathbf{c} - (\mathbf{b} \cdot \mathbf{c}) \mathbf{a} \\ & = \frac{+ (\mathbf{c} \cdot \mathbf{b}) \mathbf{a} - (\mathbf{c} \cdot \mathbf{a}) \mathbf{b}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} \\ & (\because \mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{a}) \end{aligned}$$

**Example 66.** If  $(e_1, e_2, e_3)$  and  $(e_1', e_2', e_3')$  are two sets of non-coplanar vectors such that  $\hat{\mathbf{i}} = 1, 2, 3$ ,

we have 
$$e_{\mathbf{i}} \cdot e_{\mathbf{j}}' = \begin{cases} 1, & \text{if } \hat{\mathbf{i}} = \hat{\mathbf{j}} \\ 0, & \text{if } \hat{\mathbf{i}} \neq \hat{\mathbf{j}} \end{cases}$$
, then show that  $[e_1, e_2, e_3], [e_1' e_2' e_3'] = 1.$ 

**Sol.** We have, 
$$e_1 \cdot e_2' = 0, e_1 \cdot e_3' = 0$$
  
 $\Rightarrow e_1 \perp e_2' \text{ and } e_1 \perp e_3'$   
 $\therefore e_1 || (e_2' \times e_3')$   
 $\therefore e_1 = \lambda (e_2' \times e_3')$  ...(i)  
 $e_1 \cdot e_1' = \lambda (e_2' \times e_3') \cdot e_1'$   
 $1 = \lambda [e_1' e_2' e_3']$  (::  $e_1 e_1' = 1$ , given)  
 $\lambda = \frac{1}{[e_1' e_2' e_3']}$ 

From Eq. (i),

From Eq. (1), 
$$e_{1} = \frac{e_{2}' \times e_{3}'}{[e_{1}' e_{2}' e_{3}']}$$
Similarly, 
$$e_{2} = \frac{e_{3}' \times e_{1}'}{[e_{1}' e_{2}' e_{3}']}$$
and 
$$e_{3} = \frac{e_{1}' \times e_{2}'}{[e_{1}' e_{2}' e_{3}']}$$

$$\therefore [e_{1} e_{2} e_{3}] = \frac{[e_{2}' \times e_{3}' e_{3}' \times e_{1}' e_{1}' \times e_{2}']}{[e_{1}' e_{2}' e_{3}']^{3}}$$

$$\Rightarrow [e_{1}, e_{2}, e_{3}][e_{1}' e_{2}' e_{3}']^{3} = [e_{2}' \times e_{3}' e_{3}' \times e_{1}' e_{1}' \times e_{2}'] \dots (ii)$$

Now,  $[e_{2}^{'} \times e_{3}^{'} e_{3}^{'} \times e_{1}^{'} e_{1}^{'} \times e_{2}^{'}] = [e_{1}^{'} e_{2}^{'} e_{3}^{'}]^{2}$ 

∴ From Eqs. (ii) and (iii), we get

$$[e_1 \ e_2 \ e_3] [e_1' \ e_2' \ e_3']^3 = [e_1' \ e_2' \ e_3']^2$$
$$[e_1 \ e_2 \ e_3] [e_1' \ e_2' \ e_3'] = 1$$

## **Solving of Vector Equations**

Solving a vector equation means determining an unknown vector (or a number of vectors satisfying the given conditions)

Generally, to solve vector equations we express the unknown as the linear combination of three non-coplanar vector as;  $\mathbf{r} = x\mathbf{a} + y\mathbf{b} + z(\mathbf{a} \times \mathbf{b})$ ; as  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{a} \times \mathbf{b}$  are non-coplanar and find x, y and z using given conditions. Sometimes, we can directly solve the given condition it would be more clear from some examples.

**Example 67.** Solve the vector equation  $\mathbf{r} \times \mathbf{b} = \mathbf{a} \times \mathbf{b}$ ,  $\mathbf{r} \cdot \mathbf{c} = 0$  provided that  $\mathbf{c}$  is not perpendicular to  $\mathbf{b}$ .

Sol. We are given,

$$\mathbf{r} \times \mathbf{b} = \mathbf{a} \times \mathbf{b}$$

$$\Rightarrow (\mathbf{r} - \mathbf{a}) \times \mathbf{b} = 0$$
Hence,  $(\mathbf{r} - \mathbf{a})$  and  $\mathbf{b}$  are parallel.
$$\Rightarrow \mathbf{r} - \mathbf{a} = t\mathbf{b}$$
and we known
$$\mathbf{r} \cdot \mathbf{c} = 0, \qquad ...(i)$$

$$\therefore \text{ Taking dot product of Eq. (i) by } \mathbf{c}, \text{ we get}$$

$$\mathbf{r} \cdot \mathbf{a} - \mathbf{a} \cdot \mathbf{c} = t(\mathbf{b} \cdot \mathbf{c})$$

$$\Rightarrow 0 - \mathbf{a} \cdot \mathbf{c} = t(\mathbf{b} \cdot \mathbf{c})$$

$$\Rightarrow t = -\left(\frac{\mathbf{a} \cdot \mathbf{c}}{\mathbf{b} \cdot \mathbf{c}}\right) \qquad \dots(ii)$$

 $\therefore$  From Eqs. (i) and (ii) solution of  $\mathbf{r}$  is

$$\mathbf{r} = \mathbf{a} - \left(\frac{\mathbf{a} \cdot \mathbf{c}}{\mathbf{b} \cdot \mathbf{c}}\right) \mathbf{b}$$

**Example 68.** Solve for x, such that  $A \cdot X = C$  and  $\mathbf{A} \times \mathbf{X} = \mathbf{B}$  with  $C \neq 0$ .

**Sol.** We have,  $\mathbf{A} \times \mathbf{X} = \mathbf{B}$ 

...(iii)

Taking vector product of both sides with **A**, we get

$$\mathbf{A} \times \mathbf{B} = \mathbf{A} \times (\mathbf{A} \times \mathbf{X})$$

$$= (\mathbf{A} \cdot \mathbf{X}) \mathbf{A} - (\mathbf{A} \cdot \mathbf{A}) \mathbf{X}$$

$$= \mathbf{C} \mathbf{A} - |\mathbf{A}|^2 \mathbf{X}$$

$$(\text{using } \mathbf{A} \cdot \mathbf{X} = \mathbf{C} \text{ and } \mathbf{A} \cdot t\mathbf{A} = |\mathbf{A}|^2)$$

$$\Rightarrow |\mathbf{A}|^2 \mathbf{X} = \mathbf{C} \mathbf{A} - \mathbf{A} \times \mathbf{B}$$
or
$$\mathbf{X} = \frac{\mathbf{C} \mathbf{A} + \mathbf{B} \times \mathbf{A}}{|\mathbf{A}|^2}$$

**Example 69.** Solve the vector equation  $\mathbf{r} \times \mathbf{a} + k\mathbf{r} = \mathbf{b}$ , where  $\mathbf{a}$  and  $\mathbf{b}$  are two given vector and k is any scalar.

**Sol.** Since,  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{a} \times \mathbf{b}$  are two non-coplanar vectors.

$$\mathbf{r} = x\mathbf{a} + y\mathbf{b} + z(\mathbf{a} \times \mathbf{b})$$
 ...(i) (where,  $x, y$  and  $z$  scalars)

On putting **r** in  $\mathbf{r} \times \mathbf{a} + k\mathbf{r} = \mathbf{b}$ , we get

$$\{x\mathbf{a} + y\mathbf{b} + z(\mathbf{a} \times \mathbf{b})\} \times \mathbf{a} + k\{x\mathbf{a} + y\mathbf{b} + z(\mathbf{a} \times \mathbf{b})\} = \mathbf{b}$$
  
$$\Rightarrow y(\mathbf{b} \times \mathbf{a}) + z\{(\mathbf{a} \cdot \mathbf{a})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{a}\} + k\{x\mathbf{a} + y\mathbf{b}$$

$$+z\left(\mathbf{a}\times\mathbf{b}\right)=\mathbf{b}$$

$$\Rightarrow \{kx - z(\mathbf{a} \cdot \mathbf{b})\}\mathbf{a} + \{ky + z(\mathbf{a} \cdot \mathbf{a})\}\mathbf{b} + \{(y + zk)\}(\mathbf{a} \times \mathbf{b}) = \mathbf{b}$$

$$\Rightarrow kx - z(\mathbf{a} \cdot \mathbf{b}) = 0, ky + z(\mathbf{a} \cdot \mathbf{a}) = 1$$

$$\Rightarrow$$
  $-y + zk = 0$ 

On solving these equations, we get

$$z = \frac{1}{k^2 + |\mathbf{a}|^2},$$
$$x = \frac{\mathbf{a} \cdot \mathbf{b}}{k(|\mathbf{a}|^2 + k^2)}$$

and

$$y = \frac{k}{k^2 + |\mathbf{a}|^2}$$

On putting theses value in Eq. (i), we get the solution,

$$\mathbf{r} = \frac{(\mathbf{a} \cdot \mathbf{b})}{k(k^2 + |\mathbf{a}|^2)} + \frac{k}{k^2 + |\mathbf{a}|^2} (\mathbf{b}) + \frac{1}{k^2 + |\mathbf{a}|^2} (\mathbf{a} \times \mathbf{b})$$

$$\mathbf{r} = \frac{1}{k^2 + |\mathbf{a}|^2} \left[ \frac{(\mathbf{a} \cdot \mathbf{b}) \mathbf{a}}{k} + (k) \mathbf{b} + (\mathbf{a} \times \mathbf{b}) \right]$$
is required solution.

**Example 70.** Solve for vectors **A** and **B**, where

$$\mathbf{A} + \mathbf{B} = \mathbf{a}, \ \mathbf{A} \times \mathbf{B} = \mathbf{b}, \ \mathbf{A} \cdot \mathbf{a} = 1$$

**Sol.** We have, 
$$A + B = a$$

$$\Rightarrow \mathbf{A} \cdot \mathbf{a} + \mathbf{B} \cdot \mathbf{a} = \mathbf{a} \cdot \mathbf{a}$$

$$\Rightarrow 1 + \mathbf{B} \cdot \mathbf{a} = \mathbf{a}^2 \qquad (given \mathbf{A} \cdot \mathbf{a} = 1)$$

$$\Rightarrow \mathbf{B} \cdot \mathbf{a} = \mathbf{a}^2 - 1 \qquad \dots (i)$$

Also, 
$$\mathbf{A} \times \mathbf{B} = \mathbf{b}$$

$$\Rightarrow$$
  $\mathbf{a} \times (\mathbf{A} \times \mathbf{B}) = \mathbf{a} \times \mathbf{b}$ 

$$\Rightarrow (\mathbf{a} \cdot \mathbf{B})\mathbf{A} - (\mathbf{a} \cdot \mathbf{A})\mathbf{B} = \mathbf{a} \times \mathbf{b}$$

$$\Rightarrow \qquad (\mathbf{a}^2 - 1)\mathbf{A} - \mathbf{B} = \mathbf{a} \times \mathbf{b}$$

[using Eq. (i) and  $\mathbf{a} \cdot \mathbf{A} = 1$ ] ...(ii)

and 
$$A + B = a$$

From Eqs. (i) and (ii), we get

$$A = \frac{(a \times b) + a}{a^2}$$
 and  $B = a - \left\{ \frac{(a \times b) + a}{a^2} \right\}$ 

$$\Rightarrow B = \frac{(\mathbf{b} \times \mathbf{a}) + \mathbf{a}(\mathbf{a}^2 - 1)}{\mathbf{a}^2}$$

$$\mathbf{A} = \frac{(\mathbf{a} \times \mathbf{b}) + \mathbf{a}}{\mathbf{a}^2}$$
 and  $\mathbf{B} = \frac{(\mathbf{b} \times \mathbf{a}) \mathbf{a} (\mathbf{a}^2 - 1)}{\mathbf{a}^2}$

$$-5 \le 3\cos\frac{\theta}{2} + 4\sin\frac{\theta}{2} \le 5$$

The possible range are 3, 4 or 5.

• Ex. 80 Which of the following expressions are meaningful?

(a) 
$$\mathbf{u} \cdot (\mathbf{v} \times \mathbf{w})$$

(b) 
$$(\mathbf{u} \cdot \mathbf{v}) \cdot \mathbf{w}$$

$$(c)(\mathbf{u} \cdot \mathbf{v}) \mathbf{w}$$

(d) 
$$\mathbf{u} \times (\mathbf{v} \cdot \mathbf{w})$$

**Sol.** (a, c) (i) Since,  $\mathbf{v} \times \mathbf{w}$  is a vector, therefore,  $\mathbf{u} \cdot (\mathbf{v} \times \mathbf{w})$  is a scalar quantity.

- ∴ (a) is meaningful.
- (ii)  $(\mathbf{u} \cdot \mathbf{v})$  is scalar.
- $\therefore (\mathbf{u} \cdot \mathbf{v}) \cdot \mathbf{w}$  is not meaningful.
- (iii)  $(\mathbf{u} \cdot \mathbf{v})$  is a scalar.

So,  $(\mathbf{u} \cdot \mathbf{v})\mathbf{w}$  is a scalar multiple of  $\mathbf{w}$ .

- ∴(**u** · **v**)**w** is meaningful.
- (iv)  $(\mathbf{v} \cdot \mathbf{w})$  is a scalar.

So,  $\mathbf{u} \times (\mathbf{v} \cdot \mathbf{w})$  is not meaningful as cross product is taken for two vector quantity and not for a vector and scalar.

• Ex. 81 If  $\mathbf{a} + 2\mathbf{b} + 3\mathbf{c} = 0$ , then  $\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a} = 0$ 

(a) 
$$2(\mathbf{a} \times \mathbf{b})$$

(b) 
$$6(\mathbf{b} \times \mathbf{c})$$

(c) 
$$3(\mathbf{c} \times \mathbf{a})$$

**Sol.** (a, b, c) 
$$\mathbf{a} = -(2\mathbf{b} + 3\mathbf{c})$$

$$\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a}$$

$$= -(2\mathbf{b} + 3\mathbf{c}) \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \{-(2\mathbf{b} + 3\mathbf{c})\}$$

$$= -3\mathbf{c} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} - 2\mathbf{c} \times \mathbf{b} = 6(\mathbf{b} \times \mathbf{c})$$

Similarly, putting the values of **b** and **c** in terms of **a** and **a**, **b** respectively in  $\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a}$ , we get the desired results.

• Ex. 82 Let  $\alpha = a\hat{\mathbf{i}} + b\hat{\mathbf{j}} + c\hat{\mathbf{k}}$ ,  $\beta = b\hat{\mathbf{i}} + c\hat{\mathbf{j}} + a\hat{\mathbf{k}}$  and  $\gamma = c\hat{\mathbf{i}} + a\hat{\mathbf{j}} + b\hat{\mathbf{k}}$  be three coplanar vectors with  $a \neq b$  and  $\mathbf{v} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$ . Then  $\mathbf{v}$  is perpendicular to

- (a) α
- (b) B
- (c) y
- (d) None of these

**Sol.** (a, b, c) It is given that  $\alpha,\beta$  and  $\gamma$  are coplanar vectors.

Therefore,

$$[\alpha \beta \gamma] = 0 \implies \begin{vmatrix} a & b & c \\ b & c & a \\ c & a & b \end{vmatrix} = 0$$

$$3abc - a^3 - b^3 - c^3 = 0$$

or 
$$a^3 + b^3 + c^3 - 3abc = 0$$

or 
$$(a + b + c)(a^2 + b^2 + c^2 - ab - bc - ca) = 0$$

or 
$$a+b+a$$

$$a + b + c = 0$$
 [:  $a^2 + b^2 + c^2 - ab - bc - ca \neq 0$ ]

$$\Rightarrow$$

$$\mathbf{v} \cdot \boldsymbol{\alpha} = \mathbf{v} \cdot \boldsymbol{\beta} = \mathbf{v} \cdot \boldsymbol{\gamma} = 0$$

Hence, v is perpendicular to  $\alpha$ ,  $\beta$  and  $\gamma$ 

• Ex. 83 If a is perpendicular to b and p is non-zero scalar such that  $p\mathbf{r} + (\mathbf{r} \cdot \mathbf{b})\mathbf{a} = \mathbf{c}$ , then  $\mathbf{r}$  satisfy

(a) 
$$[ r a c ] = 0$$

(b) 
$$p^2 \mathbf{r} = p\mathbf{a} - (\mathbf{c} \cdot \mathbf{a}) \mathbf{b}$$

(c) 
$$p^2 \mathbf{r} = p\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}$$
 (d)  $p^2 \mathbf{r} = p\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a}$ 

(d) 
$$p^2 \mathbf{r} = p\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})$$

**Sol.** (a, d) Given,  $\mathbf{a} \cdot \mathbf{b} = 0$ 

and 
$$p\mathbf{r} + (\mathbf{r} \cdot \mathbf{b}) \mathbf{a} = \mathbf{c}$$
 ... (i)

On taking dot product by b, we get

$$p(\mathbf{r} \cdot \mathbf{b}) + (\mathbf{r} \cdot \mathbf{b})\mathbf{a} \cdot \mathbf{b} = \mathbf{b} \cdot \mathbf{c}$$

$$\Rightarrow \qquad p(\mathbf{r} \cdot \mathbf{b}) = \mathbf{b} \cdot \mathbf{c}$$

$$\Rightarrow \qquad p\left(\frac{\mathbf{c} - pr}{\mathbf{a}}\right) = \mathbf{b} \cdot \mathbf{c}$$

$$\Rightarrow \qquad p\mathbf{c} - p^2 \mathbf{r} = (\mathbf{b} \cdot \mathbf{c})\mathbf{a}$$

$$p^2 r = p\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a}$$

$$\mathbf{r} = \frac{\mathbf{c}}{p} - \frac{(\mathbf{b} \cdot \mathbf{c})}{p^2} \mathbf{a}$$

$$\Rightarrow$$
  $[\mathbf{r} \ \mathbf{a} \ \mathbf{c}] = 0$ 

• Ex. 84 If 
$$\alpha(\mathbf{a} \times \mathbf{b}) + \beta(\mathbf{b} \times \mathbf{c}) + \gamma(\mathbf{c} \times \mathbf{a}) = 0$$
, then

- (a) **a**, **b**, **c** are coplanar if all of  $\alpha$ ,  $\beta$ ,  $\gamma \neq 0$
- (b) **a**, **b**, **c** are coplanar if any one of  $\alpha$ ,  $\beta$ ,  $\gamma \neq 0$
- (c) **a**, **b**, **c** are non-coplanar for any  $\alpha$ ,  $\beta$ ,  $\gamma \neq 0$
- (d) None of the above

**Sol.** (a, b) We have, 
$$\alpha(\mathbf{a} \times \mathbf{b}) + \beta(\mathbf{b} \times \mathbf{c}) + \gamma(\mathbf{c} \times \mathbf{a}) = 0$$

Taking dot product with c, we have

$$\alpha[\mathbf{a} \mathbf{b} \mathbf{c}] = 0$$

Similarly, taking dot product with b and c, we have

$$\gamma[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = 0, \beta[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = 0$$

Now, even if one of  $\alpha$ ,  $\beta$ ,  $\gamma \neq 0$ , then we have  $[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = 0$  $\Rightarrow$  a, b, c are coplanar.

• Ex. 85 If  $\mathbf{a} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\mathbf{b} = \hat{\mathbf{i}} - \hat{\mathbf{j}}$ , then the vectors  $(\mathbf{a} \cdot \hat{\mathbf{i}})\hat{\mathbf{i}} + (\mathbf{a} \cdot \hat{\mathbf{j}} + (\mathbf{a} \cdot \hat{\mathbf{k}})\hat{\mathbf{k}}, (\mathbf{b} \cdot \hat{\mathbf{i}})\hat{\mathbf{i}} + (\mathbf{b} \cdot \hat{\mathbf{j}})\hat{\mathbf{j}} + (\mathbf{b} \cdot \hat{\mathbf{k}})\hat{\mathbf{k}}$  and  $\hat{i} + \hat{j} - 2\hat{k}$ 

- (a) are mutually perpendicular
- (b) are coplanar
- (c) form a parallelopiped of volume 6 units
- (d) form a parallelopiped of volume 3 units

**Sol.** (a, c) Given  $\mathbf{a} = \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\mathbf{b} = \hat{\mathbf{i}} - \hat{\mathbf{j}}$

  - (b) Both Statement I and Statement II are correct but Statement II is not the correct explanation of Statement I
  - (c) Statement I is correct but Statement II is incorrect
  - (d) Statement II is correct but Statement I is incorrect

$$= \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c} + \mathbf{b} \times \mathbf{c} + \mathbf{b} \times \mathbf{a} + \mathbf{c} \times \mathbf{a} + \mathbf{c} \times \mathbf{b}$$

$$= \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c} + \mathbf{b} \times \mathbf{c} - \mathbf{a} \times \mathbf{b} - \mathbf{a} \times \mathbf{c} - \mathbf{b} \times \mathbf{c}$$

 $\therefore \mathbf{p} = -\mathbf{q} - \mathbf{r}$  (a linear combination of  $\mathbf{q}$  and  $\mathbf{r}$ )

Therefore,  $\mathbf{p}$ ,  $\mathbf{q}$ ,  $\mathbf{r}$  are coplanar and hence statement I is true.

Statement II  $p + q + r = 0 \Rightarrow p, q, r$  are not linearly independent.

Therefore, statement II is not true.

• Ex. 95 Statement I If in a  $\triangle ABC$ , BC =  $\frac{\mathbf{p}}{|\mathbf{p}|} - \frac{\mathbf{q}}{|\mathbf{q}|}$  and

 $AC = \frac{2\mathbf{p}}{|\mathbf{p}|}; |\mathbf{p}| \neq |\mathbf{q}|, \text{ then the value of } \cos 2A + \cos 2B + \cos 2C$ 

**Statement II** *If* in  $\triangle ABC$ ,  $\angle C = 90^{\circ}$ , then  $\cos 2A + \cos 2B + \cos 2C = -1$ 

#### **Sol.** (b) **Statement II** In $\triangle ABC$ , $\angle C = 90^{\circ}$

$$cos 2A + cos 2B + cos 2C$$

$$= 2 cos(A + B) cos(A - B) + cos 180^{\circ}$$

$$= cos (180^{\circ} - C) cos (A - B) - 1$$

$$= -2 cos C cos(A - B) - 1$$

$$= 0 - 1 = -1$$
 [:  $cos C = cos 90^{\circ} = 0$ ]

Therefore, Statement II is true.

**Statement I BC** =  $\hat{p} - \hat{q}$ , **AC** =  $2\hat{p}$ 

$$\therefore \mathbf{AB} = \mathbf{AC} + \mathbf{CB} = 2\hat{p} - (\hat{p} - \hat{q}) = \hat{p} + \hat{q}$$

Now, 
$$\mathbf{AB} \cdot \mathbf{BC} = (\hat{p} + \hat{q}) \cdot (\hat{p} - \hat{q}) = |\hat{p}|^2 - |\hat{q}|^2 = 1 - 1 = 0$$

$$\angle B = 90^{\circ}$$

Now,  $\cos 2A + \cos 2B + \cos 2C$ 

$$= \cos 2A + \cos 2C + \cos 2B$$

$$=2\cos(A+C)\cos(A-C)+\cos180^{\circ}$$

$$= 2\cos(180^{\circ} - B)\cos(A - C) - 1$$
  
= -2\cos B\cos(A - C) - 1 = -1 \quad (\therefore B = 90^{\circ})

Therefore, Statement I is also true.

Thus both Statements are true but Statement II is not the correct explanation of Statement I.

### • Ex. 96 Statement I If a is perpendicular to b and c, then $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = 0$

**Statement II** If **b** is perpendicular to **c**, then  $\mathbf{b} \times \mathbf{c} = 0$ **Sol.** (c) If **a** is perpendicular to **b** and **c**, then  $\mathbf{a} \parallel (\mathbf{b} \times \mathbf{c})$ 

$$\therefore \qquad \mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = 0$$

Therefore, Statement I is true.

But, if  $\mathbf{b} \perp \mathbf{c}$ , then  $\mathbf{b} \times \mathbf{c} \neq 0$ 

Therefore, Statement II is not true.

  - (d)  $\mathbf{a}$ ,  $\mathbf{a}_1$  and  $\mathbf{a}_2$  are coplanar

**Sol.** (c)  $\mathbf{a}$ ,  $\mathbf{a}_1$  and  $\mathbf{b}$  are coplanar because  $\mathbf{a}_1$  and  $\mathbf{b}$  are collinear.

Here, 
$$|\mathbf{a}| = 2, |\mathbf{b}| = 3$$

# Passage III

(Ex. Nos. 103-105)

Consider a triangular pyramid ABCD the position vectors of whose angular points are A (3, 0, 1), B (- 1, 4, 1), C (5, 2, 3) and D(0, - 5, 4). Let G be the point of intersection of the medians of triangle BCD.

• Ex. 103 The length of vector AG is

- (d) None of these

**Sol.** For (Ex. Nos. 103-105)

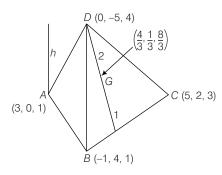

Point G is  $\left(\frac{4}{3}, \frac{1}{3}, \frac{8}{3}\right)$ . Therefore,

$$|\mathbf{AG}|^2 = \left(\frac{5}{3}\right)^2 + \frac{1}{9} + \left(\frac{5}{3}\right)^2 = \frac{51}{9}$$

or  $|\mathbf{AG}| = \frac{\sqrt{51}}{3}$ 

$$\mathbf{A}\mathbf{B} = -4\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 0\hat{\mathbf{k}}$$

$$\mathbf{AC} = 2\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$$

AB × AC =

# Passage IV

(Ex. Nos. 106-108)

Let A, B, C represent the vertices of a triangle, where A is the origin and B and C have position vectors **b** and **c** respectively. Points M, N and P are taken on sides AB, BC

and CA respectively, such that  $\frac{AM}{AB} = \frac{BN}{BC} = \frac{CP}{CA} = \alpha$ 

[Now answer the following questions]

#### • Ex. 106. AN + BP + CM is

- (a)  $3\alpha (b + c)$
- (b)  $\alpha(\mathbf{b} + \mathbf{c})$
- $(c)(1-\alpha)(\mathbf{b}+\mathbf{c})$
- (d)0

**Sol.** (d) Since 
$$\frac{AM}{AB} = \alpha$$
,

$$\therefore$$
 **P.V.** of **M** =  $\alpha$  **b**

Since, 
$$\frac{BN}{BC} = 0$$

$$\therefore \frac{BN}{NC} = \frac{\alpha}{1-\alpha}$$

∴ Position vector of  $\mathbf{N} = (1 - \alpha)\mathbf{b} + \alpha\mathbf{c}$ 

Since, 
$$\frac{CP}{CA} = \alpha$$

$$\therefore \frac{AP}{RR} = \frac{1-\alpha}{2}$$

$$\mathbf{p} = (1 - \alpha)\mathbf{c}$$

$$\mathbf{AN} = (1 - \alpha)\mathbf{b} + \alpha\mathbf{c}$$

$$\mathbf{BP} = (1 - \alpha)\mathbf{c} - \mathbf{b}$$

$$CM = \alpha b - c$$

$$\therefore$$
 AN + BP + CM = 0

#### • Ex. 107. The vectors AN, BP and CM are

- (a) concurrent
- (b) sides of a triangle
- (c) non-coplanar
- (d) None of these

**Sol.** (b) Since 
$$AN + BP + CM = 0$$

Hence, AN, BP and CM from the sides of a triangle.

## **Ex. 108.** If $\Delta$ represents the area enclosed by the three vectors **AN**, **BP** and **CM**, then the value of $\alpha$ for which $\Delta$ is least

- (a) does not exist
- (c)  $\frac{1}{4}$
- (d) None of these

Sol. (b) 
$$\Delta = \frac{1}{2} |\mathbf{AN} \times \mathbf{BP}| = \frac{1}{2} |\{(1 - \alpha)\mathbf{b} + \alpha\mathbf{c}\} \times \{(1 - \alpha)\mathbf{c} - \mathbf{b}\}|$$

$$= \frac{1}{2} |(1 - \alpha)^2 (\mathbf{b} \times \mathbf{c}) + \alpha (\mathbf{b} \times \mathbf{c})|$$

$$= \frac{1}{2} |\mathbf{b} \times \mathbf{c}| (\alpha^2 - \alpha + 1)$$

$$= \frac{1}{2} |\mathbf{b} \times \mathbf{c}| \left\{ \left(\alpha - \frac{1}{2}\right)^2 + \frac{3}{4} \right\}$$

$$\therefore \Delta$$
 is least, if  $\alpha = \frac{1}{2}$

(c) 
$$\cos^{-1}\left(\frac{\sqrt{7}}{3}\right)$$
 (d)  $\frac{\pi}{3}$ 

(d) 
$$\frac{\pi}{3}$$

**Sol.** For (Ex. Nos. 109-110)

Since, sum of three vectors 9AP, 4BQ and 7CR is zero, there is a  $\Delta$  whose sides have lengths 9| **AP**|, 4| **BQ**, 7| **CR**| and are parallel to the corresponding vectors.

*H* is orthocentre.

$$\Rightarrow \angle BHP = 90^{\circ} - \angle QBC = \angle ACB$$

 $\Rightarrow$  Angle between **AP** and **BO** equal to  $\angle ACB$ , similarly angle between **BQ** and **CR** be  $\angle BAC$ .

$$\Rightarrow \frac{AB}{7|\mathbf{CR}|} = \frac{BC}{9|\mathbf{AP}|} = \frac{AC}{4|\mathbf{BQ}|}$$

2. ar. 
$$(\Delta ABC) = |\mathbf{AB} \times \mathbf{CR}| = |\mathbf{BC} \times \mathbf{AP}| = |\mathbf{CA} \times \mathbf{BQ}|$$

$$\Rightarrow \frac{c^2}{7} = \frac{a^2}{9} = \frac{b^2}{4}$$

$$a:b:c=3:2:\sqrt{7}$$

$$\Rightarrow \qquad \cos C = \frac{a^2 + b^2 - c^2}{2ab} = \frac{1}{2}$$

$$\Rightarrow$$
  $\angle C = 60^{\circ} = \frac{\pi}{3}$ 

and 
$$\cos B = \frac{a^2 + b^2 - c^2}{2ac} = \frac{2}{\sqrt{7}}$$

## Passage VI

(Ex. Nos. 111 to 113)

Let  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$  are non-zero unit vectors inclined pairwise with the same angle  $\mathbf{\theta}$ . p, q, r are non-zero scalars satisfying  $\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} = p\mathbf{a} + q\mathbf{b} + r\mathbf{c}$ 

• Ex. 111 Volume of parallelopiped with edges a, b and c is

(a) 
$$p + (q + r)\cos\theta$$

(b) 
$$(p + q + r)\cos\theta$$

(c) 
$$2p - (q + r)\cos\theta$$

(d) None of these

• **Ex. 112** The value of 
$$\left(\frac{q}{p} + 2\cos\theta\right)$$
 is

(a)

(b) 0

(d) None of these

• **Ex. 113** The value of  $|(p+q)\cos\theta + r|$  is

(a) 
$$(1 + \cos\theta)\sqrt{1 - 2\cos\theta}$$

(b) 
$$2\sin^2\frac{\theta}{2}|\sqrt{1+2\cos\theta}|$$

(c) 
$$(1 - \sin\theta)\sqrt{1 + 2\cos\theta}$$

(d) None of the above

**Sol.** For (Ex. Nos. 111-113)

Volume of parallelopiped =  $[a\ b\ c] = a\ .\ (b \times c)$ 

Now, we have

$$\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} = p\mathbf{a} + q\mathbf{b} + r\mathbf{c}$$

$$\Rightarrow$$
  $\mathbf{a} \cdot (\mathbf{a} \times \mathbf{b}) + \mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = p(\mathbf{a} \cdot \mathbf{a}) + q(\mathbf{a} \cdot \mathbf{b}) + r(\mathbf{a} \cdot \mathbf{c})$ 

$$\Rightarrow [\mathbf{a} \ \mathbf{a} \ \mathbf{b}] + [\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = p|\mathbf{a}|^2 + q|\mathbf{a}||\mathbf{b}|\cos\theta + r|\mathbf{a}||\mathbf{c}|\cos\theta$$

$$\Rightarrow$$
 [a b c] =  $p + q\cos\theta + r\cos\theta = p + (q + r)\cos\theta$ 

∴Volume of parallelopiped =  $p + (q + r)\cos\theta$ 

Taking dot products with  $\mathbf{a},\,\mathbf{b},\,\mathbf{c}$  respectively with given equation

$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = p + (q + r)\cos\theta \qquad \dots (i)$$

$$0 = (p+r)\cos\theta + q \qquad ...(ii)$$

...(iii)

$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = (p+q)\cos\theta + r$$
Also, 
$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2 = \begin{vmatrix} 1 & \cos\theta & \cos\theta \\ \cos\theta & 1 & \cos\theta \end{vmatrix}$$

$$\begin{vmatrix} \cos\theta & \cos\theta & 1 \end{vmatrix}$$

$$\Rightarrow \qquad [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2 = (1 - \cos\theta)^2 (1 + 2\cos\theta)$$

$$\therefore \qquad v = |[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]| = |1 - \cos\theta| |\sqrt{1 + 2\cos\theta}|$$

$$=2\sin^2\frac{\theta}{2}.|\sqrt{1+2\cos\theta}|$$

From Eqs. (i) and (iii), p = r substituting in Eq. (ii), we get

$$2p\cos\theta + q = 0$$

$$\Rightarrow \frac{q}{p} + 2\cos\theta = 0$$

So, 
$$[(a-2)\alpha^2 + (b-3)\alpha + c]\mathbf{x} + [(a-2)\beta^2 + (b-3)\beta + c]\mathbf{y} + [(a-2)\gamma^2 + (b-3)\gamma + c](\mathbf{x} \times \mathbf{y}) = 0$$

 $\Rightarrow$  Coefficient of each vector  $\mathbf{x}$ ,  $\mathbf{y}$  and  $\mathbf{x} \times \mathbf{y}$  is zero.

$$(a-2) \alpha^{2} + (b-3)\alpha + c = 0$$

$$(a-2) \beta^{2} + (b-3) \beta + c = 0$$

$$(a-2) \gamma^{2} + (b-3) \gamma + c = 0$$

The above three equations will satisfy if the coefficients of  $\alpha$ ,  $\beta$  and  $\gamma$  are zero because  $\alpha$ ,  $\beta$  and  $\gamma$  are three distinct real numbers

$$\Rightarrow (\hat{\mathbf{a}} + \hat{\mathbf{b}}) \cdot (\hat{\mathbf{a}} + \hat{\mathbf{b}}) = 1$$

$$\Rightarrow \hat{\mathbf{a}} \cdot \hat{\mathbf{a}} + \hat{\mathbf{b}} \cdot \hat{\mathbf{b}} + 2\hat{\mathbf{a}} \cdot \hat{\mathbf{b}} = 1 \Rightarrow 1 + 1 + 2\hat{\mathbf{a}} \cdot \hat{\mathbf{b}} = 1$$

$$\Rightarrow \hat{\mathbf{a}} \cdot \hat{\mathbf{b}} = -\frac{1}{2} \Rightarrow |\hat{\mathbf{a}}| |\hat{\mathbf{b}}| \cos\theta = -\frac{1}{2}$$

$$\Rightarrow \cos\theta = -\frac{1}{2} \qquad (\because |\hat{\mathbf{a}}| = |\hat{\mathbf{b}}| = 1)$$

By definition

$$\mathbf{OP} \cdot \mathbf{OQ} = |\mathbf{OP}| |\mathbf{OQ}| \cos \angle POQ = r_1 r \cos(A - B)$$

• Ex. 155 Let a and b be given non-zero and non-collinear vectors, such that  $\mathbf{c} \times \mathbf{a} = \mathbf{b} - \mathbf{c}$ . Express c in terms of a, b and  $\mathbf{a} \times \mathbf{b}$ 

Sol. Let 
$$\mathbf{c} = x_1 \mathbf{a} + x_2 \mathbf{b} + x_3 (\mathbf{a} \times \mathbf{b})$$
  
 $\Rightarrow \mathbf{c} \times \mathbf{a} = x_2 (\mathbf{b} \times \mathbf{a}) - x_3 \mathbf{a} \times (\mathbf{a} \times \mathbf{b})$   
 $= x_2 (\mathbf{b} \times \mathbf{a}) - x_3 (\mathbf{a} \cdot \mathbf{b}) \mathbf{a} + x_3 |\mathbf{a}|^2 \mathbf{b}$   
We have been given,  $\mathbf{c} \times \mathbf{a} = \mathbf{b} - \mathbf{c}$   
 $\Rightarrow \mathbf{b} - x_1 \mathbf{a} - x_2 \mathbf{b} - x_3 (\mathbf{a} \times \mathbf{b}) = -x_2 (\mathbf{a} \times \mathbf{b}) - x_3 (\mathbf{a} \cdot \mathbf{b}) \mathbf{a} + x_3 |\mathbf{a}|^2 \mathbf{b}$   
 $\Rightarrow x_3 \{ (\mathbf{a} \cdot \mathbf{b}) - x_1 \} \mathbf{a} + (1 - x_2 - x_3 |\mathbf{a}|^2) \mathbf{b} + (x_2 - x_3) (\mathbf{a} \times \mathbf{b}) = 0$   
Now,  $\mathbf{a}$ ,  $\mathbf{b}$  and  $\mathbf{a} \times \mathbf{b}$  are linearly independent.  
Hence,  $x_3 (\mathbf{a} \cdot \mathbf{b}) = x_1$ ,  $1 = x_2 + x_3 |\mathbf{a}|^2$ ,  $x_2 = x_3$ 

Hence, 
$$x_3(\mathbf{a} \cdot \mathbf{b}) = x_1, 1 = x_2 + x_3|\mathbf{a}|^2, x_2 = x_3$$
  

$$x_2 = x_3 = \frac{1}{1 + |\mathbf{a}|^2} \text{ and } x_1 = \frac{\mathbf{a} \cdot \mathbf{b}}{1 + |\mathbf{a}|^2}$$

# Solutions

1. Since, 
$$\mathbf{a} \perp \mathbf{b} \implies \mathbf{a} \cdot \mathbf{b} = 0$$
  
 $|\mathbf{a} - \mathbf{b}|^2 = (\mathbf{a} - \mathbf{b})^2 = \mathbf{a}^2 + \mathbf{b}^2 - 2 \mathbf{a} \cdot \mathbf{b} = 25 + 25$   
 $\implies |\mathbf{a} - \mathbf{b}| = 5\sqrt{2}$ 

2. 
$$|a + b| > |a - b|$$

On squaring both sides, we get

$$\mathbf{a}^2 + \mathbf{b}^2 + 2\mathbf{a} \cdot \mathbf{b} > \mathbf{a}^2 + \mathbf{b}^2 - 2\mathbf{a} \cdot \mathbf{b}$$

$$\Rightarrow$$
  $4\mathbf{a} \cdot \mathbf{b} > 0 \Rightarrow \cos \theta > 0$ 

Hence,  $\theta$  < 90° (acute)

**3.** Given that, 
$$\mathbf{a} = \mathbf{b} + \mathbf{c}$$
 and angle between  $\mathbf{b}$  and  $\mathbf{c}$  is  $\frac{\pi}{2}$ 

So, 
$$\mathbf{a}^{2} = \mathbf{b}^{2} + \mathbf{c}^{2} + 2\mathbf{b} \cdot \mathbf{c}$$

$$\Rightarrow \qquad \mathbf{a}^{2} = \mathbf{b}^{2} + \mathbf{c}^{2} + 2|\mathbf{b}| |\mathbf{c}| \cos \frac{\pi}{2}$$

$$\Rightarrow \qquad \mathbf{a}^{2} = \mathbf{b}^{2} + \mathbf{c}^{2} + 0$$

$$\therefore \qquad \mathbf{a}^{2} = \mathbf{b}^{2} + \mathbf{c}^{2}$$
i.e., 
$$\mathbf{a}^{2} = \mathbf{b}^{2} + \mathbf{c}^{2}$$

- **4.** Obviously, **a** and **b** are unit vectors.
- **5.** Angle between  $\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\hat{\mathbf{i}}$  is equal to

$$\cos^{-1}\left\{\frac{(\hat{\mathbf{i}}+\hat{\mathbf{j}}+\hat{\mathbf{k}})\cdot\hat{\mathbf{i}}}{|\hat{\mathbf{i}}+\hat{\mathbf{j}}+\hat{\mathbf{k}}||\hat{\mathbf{i}}|}\right\} \implies a = \cos^{-1}\left(\frac{1}{\sqrt{3}}\right)$$

Similarly, angle between  $\hat{i} + \hat{j} + \hat{k}$  and  $\hat{j}$  is

$$\beta = \cos^{-1}\left(\frac{1}{\sqrt{3}}\right) \text{ and between } \hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}} \text{ and } \hat{\mathbf{k}} \text{ is}$$

$$\gamma = \cos^{-1}\left(\frac{1}{\sqrt{3}}\right)$$

Hence, 
$$a = \beta = \gamma$$

**6.** Let 
$$\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{i}} \Rightarrow \mathbf{r} \cdot \hat{\mathbf{i}} = x, \mathbf{r} \cdot \hat{\mathbf{j}} = y, \mathbf{r} \cdot \hat{\mathbf{k}} = z$$
  

$$\Rightarrow (\mathbf{r} \cdot \hat{\mathbf{i}})^2 + (\mathbf{r} \cdot \hat{\mathbf{j}})^2 + (\mathbf{r} \cdot \hat{\mathbf{k}})^2 = x^2 + y^2 + z^2 = r^2$$

7. 
$$|\mathbf{a} - \mathbf{b}| = \sqrt{1^2 + 1^2 - 2 \cdot 1^2 \cos \theta} = \sqrt{2(1 - \cos \theta)}$$
  
=  $\sqrt{2} \times \sqrt{2} \sin \frac{\theta}{2} = 2\sin \frac{\theta}{2} \implies \sin \frac{\theta}{2} = \frac{|\mathbf{a} - \mathbf{b}|}{2}$ 

**8.** The component of vector  $\mathbf{a}$  along  $\mathbf{b}$  is

$$\frac{(\mathbf{a} \cdot \mathbf{b})\mathbf{b}}{|\mathbf{b}|^2} = \frac{18}{25} (3\hat{\mathbf{j}} + 4\hat{\mathbf{k}})$$

**9.** Required value = 
$$\frac{\mathbf{b} \cdot \mathbf{a}}{|\mathbf{b}|} / \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|} = \frac{|\mathbf{a}|}{|\mathbf{b}|} = \frac{7}{3}$$

**10.** 
$$(\mathbf{a} \times \mathbf{b})^2 = a^2 b^2 - (\mathbf{a} \cdot \mathbf{b})^2 = \begin{vmatrix} \mathbf{a} \cdot \mathbf{a} & \mathbf{a} \cdot \mathbf{b} \\ \mathbf{b} \cdot \mathbf{a} & \mathbf{b} \cdot \mathbf{b} \end{vmatrix}$$

**11.** Torque =  $\mathbf{r} \times \mathbf{F}$  or  $\mathbf{CP} \times \mathbf{F}$ 

**12.** 
$$\mathbf{r} \times \mathbf{F} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & -1 & 1 \\ 1 & 2 & 3 \end{vmatrix} = -5\hat{\mathbf{i}} - 5\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$$

**13.** OA = 
$$3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 9\hat{\mathbf{k}}, \mathbf{F} = (9\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 2\hat{\mathbf{k}}) \times \frac{6}{11}$$

$$\therefore \quad \text{Moment} = \mathbf{OA} \times \mathbf{F} = \frac{6}{11} \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 3 & 2 & -9 \\ 9 & 6 & -2 \end{vmatrix}$$

$$= \frac{6}{11} (50\hat{\mathbf{i}} - 75\hat{\mathbf{j}}) = \frac{150}{11} (2\hat{\mathbf{i}} - 3\hat{\mathbf{j}})$$

**14.** Force  $(\mathbf{F}) = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} - \hat{\mathbf{k}}$  and its position vector  $= 2\hat{\mathbf{i}} - \hat{\mathbf{j}}$ . We know that the position vector of a force about origin  $(\mathbf{r}) = (2\hat{\mathbf{i}} - \hat{\mathbf{j}}) - (0\hat{\mathbf{i}} + 0\hat{\mathbf{j}} + 0\hat{\mathbf{k}})$  or  $\mathbf{r} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}}$  Therefore, moment of the force about origin

$$= \mathbf{r} \times \mathbf{F} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & -1 & 0 \\ 2 & 1 & -1 \end{vmatrix} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}.$$

**15.** 
$$\mathbf{a}^{-1} = \frac{\mathbf{b} \times \mathbf{c}}{[\mathbf{a}\mathbf{b}\mathbf{c}]}, \ \mathbf{c}^{-1} = \frac{\mathbf{a} \times \mathbf{b}}{[\mathbf{a}\mathbf{b}\mathbf{c}]}, \ \mathbf{b}^{-1} = \frac{\mathbf{c} \times \mathbf{a}}{[\mathbf{a}\mathbf{b}\mathbf{c}]}$$

$$\Rightarrow [\mathbf{a}^{-1} \ \mathbf{b}^{-1} \ \mathbf{c}^{-1}] = \frac{(\mathbf{b} \times \mathbf{c})}{[\mathbf{a}\mathbf{b}\mathbf{c}]} \cdot \left(\frac{(\mathbf{c} \times \mathbf{a})}{[\mathbf{a}\mathbf{b}\mathbf{c}]} \times \frac{(\mathbf{a} \times \mathbf{b})}{[\mathbf{a}\mathbf{b}\mathbf{c}]}\right)$$

$$= \frac{\mathbf{b} \times \mathbf{c}}{[\mathbf{a}\mathbf{b}\mathbf{c}]} \cdot \frac{\mathbf{a}}{[\mathbf{a}\mathbf{b}\mathbf{c}]} = \frac{1}{[\mathbf{a}\mathbf{b}\mathbf{c}]} \neq 0$$

16. 
$$\frac{\mathbf{a} \cdot \mathbf{b} \times \mathbf{c}}{\mathbf{c} \times \mathbf{a} \cdot \mathbf{b}} + \frac{\mathbf{b} \cdot \mathbf{a} \times \mathbf{c}}{\mathbf{c} \cdot \mathbf{a} \times \mathbf{b}} = \frac{[\mathbf{abc}]}{[\mathbf{cab}]} + \frac{[\mathbf{bac}]}{[\mathbf{cab}]}$$
$$= \frac{[\mathbf{abc}]}{[\mathbf{cab}]} - \frac{[\mathbf{abc}]}{[\mathbf{cab}]} = 0$$

- **17.**  $\mathbf{b} \times \mathbf{c}$  is a vector perpendicular to  $\mathbf{b}$ ,  $\mathbf{c}$ . Therefore,  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c})$  is a vector again in plane of  $\mathbf{b}$ ,  $\mathbf{c}$ .
- **18.** Let  $\mathbf{a} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$  $\mathbf{u} = \hat{\mathbf{i}} \times (\mathbf{a} \times \hat{\mathbf{i}}) + \hat{\mathbf{j}} \times (\mathbf{a} \times \hat{\mathbf{i}}) + \hat{\mathbf{k}} \times (\mathbf{a} \times \hat{\mathbf{k}})$   $= (\hat{\mathbf{i}} \cdot \hat{\mathbf{i}})\mathbf{a} - \hat{\mathbf{i}}(\mathbf{a} \cdot \hat{\mathbf{i}}) + (\hat{\mathbf{j}} \cdot \hat{\mathbf{j}})\mathbf{a} - \hat{\mathbf{j}}(\mathbf{a} \cdot \hat{\mathbf{j}})$   $+ (\hat{\mathbf{k}} \cdot \hat{\mathbf{k}})\mathbf{a} - \hat{\mathbf{k}}(\mathbf{a} \cdot \hat{\mathbf{k}}) = 3\mathbf{a} - \mathbf{a} = 2\mathbf{a}$

19. 
$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \mathbf{a} \times \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & -1 & 1 \\ 1 & 3 & -1 \end{vmatrix} = \mathbf{a} \times (-2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 7\hat{\mathbf{k}})$$

$$= \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & 2 & -2 \\ -2 & 3 & 7 \end{vmatrix} = 20\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 7\hat{\mathbf{k}}$$

**20.** 
$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = 0$$
  
 $\Rightarrow \qquad \mathbf{a} \mid\mid (\mathbf{b} \times \mathbf{c}) \text{ or } \mathbf{b} \times \mathbf{c} = 0$   
i.e.,  $\mathbf{b} \mid\mid \mathbf{c} \text{ or } \mathbf{a} = 0$ 

**21.** Let the required vector be  $\alpha = d_1 \hat{\bf i} + d_2 \hat{\bf j} + d_3 \hat{\bf k}$  where,  $d_1^2 + d_2^2 + d_3^2 = 51$  (given) ...(i)

Now, each of the given vectors **a**, **b** and **c** is a unit vectors.

$$\cos\theta = \frac{\mathbf{d} \cdot \mathbf{a}}{|\mathbf{d}| |\mathbf{a}|} = \frac{\mathbf{d} \cdot \mathbf{b}}{|\mathbf{d}| |\mathbf{b}|} = \frac{\mathbf{d} \cdot \mathbf{c}}{|\mathbf{d}| |\mathbf{c}|}$$

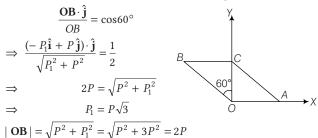

or  $\mathbf{d} \cdot \mathbf{a} = \mathbf{d} \cdot \mathbf{b} = \mathbf{d} \cdot \mathbf{c}$  $|\mathbf{d}| = \sqrt{51} \text{ cancels out and } |\mathbf{a}| = |\mathbf{b}| = |\mathbf{c}| = 1$ 

Hence, 
$$\frac{1}{3}(d_1 - 2d_2 + 2d_3) = \frac{1}{5}(-4d_1 + 0d_2 - 3d_3) = d_2$$

$$\Rightarrow d_1 - 5d_2 + 2d_3 = 0$$
and  $4d_1 + 5d_2 + 3d_3 = 0$ 
On solving, we get  $\frac{d_1}{5} = \frac{d_2}{-1} = \frac{d_3}{-5} = \lambda$  (say)

Putting  $d_1$ ,  $d_2$  and  $d_3$  in Eq. (i), we get  $\lambda = \pm 1$ Hence, the required vectors are  $\pm (5\hat{\mathbf{i}} - \hat{\mathbf{j}} - 5\hat{\mathbf{k}})$ 

**22.** Let

$$|\mathbf{x}|^2 = (\mathbf{y} + \mathbf{z}) \cdot (\mathbf{y} + \mathbf{z})$$

$$\implies |\mathbf{x}|^2 = |\mathbf{y}|^2 + |\mathbf{z}|^2 + 2\mathbf{y} \cdot \mathbf{z}$$

$$\implies |\mathbf{x}|^2 = |\mathbf{y}|^2 + |\mathbf{z}|^2 + 2|\mathbf{y}| |\mathbf{z}| \cos\theta$$

$$\implies 4 = 4 + 4 + 2 \times 2 \times 2 \cos\theta$$

$$\implies \cos\theta = \frac{-1}{2} \implies \theta = 120^\circ$$

 $\therefore \csc^2 120^\circ + \cot^2 120^\circ$ 

$$= \left(\frac{2}{\sqrt{3}}\right)^2 + \left(-\frac{1}{\sqrt{3}}\right)^2 = \frac{4}{3} + \frac{1}{3} = \frac{5}{3}$$

 $\Rightarrow \qquad \mathbf{q}^2 = 4\mathbf{p}^2$  ...(ii)  
Now,  $\cos \theta = \frac{\mathbf{p} \cdot \mathbf{q}}{|\mathbf{p}| |\mathbf{q}|}$ 

On substituting  $\mathbf{q}^2 = 4\mathbf{p}^2$  in Eq. (i), we get

$$\Rightarrow 3\mathbf{p}^2 = 4\mathbf{p} \cdot \mathbf{q}$$

$$\cos \theta = \frac{3}{4} \cdot \frac{\mathbf{p}^2}{|\mathbf{p}| 2|\mathbf{p}|} = \frac{3}{8} \Rightarrow \sin \theta = \frac{\sqrt{55}}{8}$$

 $\mathbf{u} \cdot \hat{\mathbf{n}} = 0 \implies a_1 + a_2 = 0$   
Also,  $\mathbf{v} \cdot \hat{\mathbf{n}} = 0 \implies a_1 - a_2 = 0$   
Hence,  $a_1 = a_2 = 0$   
 $\therefore$   $a_3 = 1 \text{ or } -1$

 $A(\text{origin})$   $B(\mathbf{a})$ 

On substituting the value of  $\mathbf{a} \cdot \mathbf{b}$  from Eq. (ii) in Eq. (i), we get

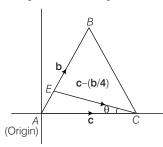

$$a^{2} - \frac{1}{2}(c^{2} - a^{2} - b^{2})$$

$$\Rightarrow \frac{3a^{2} + b^{2} - c^{2}}{2}$$

**31.** Given,

 and  $|\mathbf{c}| = 12$  ...(i)  $\mathbf{AE} = \frac{\mathbf{b}}{4}$  and  $\mathbf{EC} = \mathbf{c} - \frac{\mathbf{b}}{4}$ 

$$\cos \theta = \frac{\mathbf{c} \cdot \left(\mathbf{c} - \frac{\mathbf{b}}{4}\right)}{|\mathbf{c}| |\mathbf{c} - \frac{\mathbf{b}}{4}|} = \frac{\mathbf{c}^2 - \frac{\mathbf{c} \cdot \mathbf{b}}{4}}{12 |\mathbf{c} - \frac{\mathbf{b}}{4}|} \qquad \dots(ii)$$

From Eq. (i), 
$$|\mathbf{b}| = 8$$
,  $|\mathbf{c}| = 12$   

$$\therefore \qquad |\mathbf{b} - \mathbf{c}|^2 = |\mathbf{b}|^2$$

$$\Rightarrow |\mathbf{b}|^2 + |\mathbf{c}|^2 - 2\mathbf{b} \cdot \mathbf{c} = |\mathbf{b}|^2$$

$$\Rightarrow \qquad \mathbf{b} \cdot \mathbf{c} = 72 \qquad \dots(iii)$$

$$= 144 + 4 - 36 = 112$$

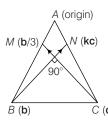

$$\therefore \qquad \left| \mathbf{c} - \frac{\mathbf{b}}{4} \right| = 4\sqrt{7} \qquad \dots(iv)$$

 D(d)  
Let  $|AC | = \lambda > 0$   
 $\therefore |AB | = 5\lambda$   
 $|AD | = 3\lambda$ 

Now, numerator of Eq. (i), we get

$$= (5\lambda)(\lambda) \frac{1}{2} + 5\lambda(3\lambda) \frac{1}{2}$$
$$= \frac{5\lambda^2 + 15\lambda^2}{2} = 10\lambda^2$$

Denominator of Eq. (i)

Now, 
$$|\mathbf{d} - \mathbf{c}|^2 = \mathbf{d}^2 + \mathbf{c}^2 - 2\mathbf{c} \cdot \mathbf{d}$$
  

$$= 9\lambda^2 + \lambda^2 - 2(\lambda)(3\lambda)\frac{1}{2}$$

$$\therefore \mathbf{y} = \frac{3}{2} \left(2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}} - \frac{2}{3}\hat{\mathbf{j}} - \frac{4}{3}\hat{\mathbf{k}}\right) = \frac{3}{2} \frac{(6\hat{\mathbf{i}} - 8\hat{\mathbf{j}} + \hat{\mathbf{k}})}{3}$$

**Solutions** (Q.Nos. 131-134)

**131.** Since, **a**, **b**, **c** are non-coplanar vectors, then

$$[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \neq 0 \implies [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2 \neq 0$$

$$\Rightarrow [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2 = \begin{vmatrix} \mathbf{a} \cdot \mathbf{a} & \mathbf{b} \cdot \mathbf{a} & \mathbf{c} \cdot \mathbf{a} \\ \mathbf{a} \cdot \mathbf{b} & \mathbf{b} \cdot \mathbf{b} & \mathbf{c} \cdot \mathbf{b} \\ \mathbf{a} \cdot \mathbf{c} & \mathbf{b} \cdot \mathbf{c} & \mathbf{c} \cdot \mathbf{c} \end{vmatrix} \neq 0$$

Since, any vector  $\mathbf{r}$  in space can be expressed as a linear combination of three non-coplanar vectors.

So, let 
$$\mathbf{r} = l\mathbf{a} + m\mathbf{b} + n\mathbf{c}$$
 ...(i)

taking dot product by a, b, c successively, we get

$$\mathbf{r} \cdot \mathbf{a} = l \, \mathbf{a} \cdot \mathbf{a} + m \, \mathbf{b} \cdot \mathbf{a} + n \mathbf{c} \cdot \mathbf{a} \qquad \dots (ii)$$

$$\mathbf{r} \cdot \mathbf{b} = l \mathbf{a} \cdot \mathbf{b} + m \mathbf{b} \cdot \mathbf{b} + n \mathbf{c} \cdot \mathbf{b}$$
 ...(iii)

$$\mathbf{r} \cdot \mathbf{c} = l \mathbf{a} \cdot \mathbf{c} + m \mathbf{b} \cdot \mathbf{c} + n \mathbf{c} \cdot \mathbf{c}$$
 ...(iv)

Now, eliminating l, m and n from above 4 relations, we get

$$\begin{vmatrix} \mathbf{r} & \mathbf{a} & \mathbf{b} & \mathbf{c} \\ \mathbf{r} \cdot \mathbf{a} & \mathbf{a} \cdot \mathbf{a} & \mathbf{b} \cdot \mathbf{a} & \mathbf{c} \cdot \mathbf{a} \\ \mathbf{r} \cdot \mathbf{b} & \mathbf{a} \cdot \mathbf{b} & \mathbf{b} \cdot \mathbf{b} & \mathbf{c} \cdot \mathbf{b} \end{vmatrix} = 0$$

Now, expanding along first row, we get

$$r = \left(\frac{\Delta_1}{\Delta}\right) \mathbf{a} + \left(\frac{\Delta_2}{\Delta}\right) \mathbf{b} + \left(\frac{\Delta_3}{\Delta}\right) \mathbf{c}$$

132. Since, a, b, c are three non-coplanar vectors, then

On three exists scalars x, y, z, such that

$$\mathbf{r} = x\mathbf{a} + y\mathbf{b} + z\mathbf{c} \qquad \dots(i)$$

Taking dot product by  $b\times c,\, c\times a$  and  $a\times b$  successively, we get

$$\mathbf{r} \cdot (\mathbf{b} \times \mathbf{c}) = (x\mathbf{a} + y\mathbf{b} + z\mathbf{c}) \cdot (\mathbf{b} \times \mathbf{c}) = x[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]$$

$$\mathbf{r} \cdot (\mathbf{c} \times \mathbf{a}) = y[\mathbf{b} \ \mathbf{c} \ \mathbf{a}]$$

$$\mathbf{r} \cdot (\mathbf{a} \times \mathbf{b}) = z[\mathbf{c} \ \mathbf{a} \ \mathbf{b}]$$

$$x = \frac{[\mathbf{r} \ \mathbf{b} \ \mathbf{c}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}, y = \frac{[\mathbf{r} \ \mathbf{c} \ \mathbf{a}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} \text{ and } z = \frac{[\mathbf{r} \ \mathbf{a} \ \mathbf{b}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}$$

On substituting the values of x, y, z in Eq. (i), we get

$$r = \left\{ \frac{[\mathbf{r} \ \mathbf{b} \ \mathbf{c}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} \right\} \mathbf{a} + \left\{ \frac{[\mathbf{r} \ \mathbf{c} \ \mathbf{a}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} \right\} \mathbf{b} + \left\{ \frac{[\mathbf{r} \ \mathbf{a} \ \mathbf{b}]}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} \right\} \mathbf{c}$$

or 
$$r = \frac{1}{[a b c]} \{ [r b c] a + [r c a] b + [r a b] c \}$$

133. We know that,

$$[\mathbf{a} \times \mathbf{b} \ \mathbf{b} \times \mathbf{c} \ \mathbf{c} \times \mathbf{a}] = [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2$$

Clearly, 
$$[\mathbf{a} \times \mathbf{b} \ \mathbf{b} \times \mathbf{c} \ \mathbf{c} \times \mathbf{a}] \neq 0\{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] \neq 0\}$$

 $\Rightarrow$  **a**×**b b**×**c c**×**a** are non-coplanar.

We also know that any vector in space can be expressed as a linear combination of any three non-coplanar vectors, so let.

$$\mathbf{a} = l(\mathbf{b} \times \mathbf{c}) + m(\mathbf{c} \times \mathbf{a}) + n(\mathbf{a} \times \mathbf{b}) \qquad \dots(i)$$

On taking dot product on both sides by  $a,\,b,\,c$  successively, we get

$$\mathbf{a} \cdot \mathbf{a} = l \ [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]$$

$$\mathbf{a} \cdot \mathbf{b} = m \ [\mathbf{c} \ \mathbf{a} \ \mathbf{b}]$$

$$\mathbf{c} \cdot \mathbf{a} = n \ [\mathbf{c} \ \mathbf{a} \ \mathbf{b}]$$

$$l = \frac{\mathbf{a} \cdot \mathbf{a}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}, m = \frac{\mathbf{a} \cdot \mathbf{b}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]} \text{ and } n = \frac{\mathbf{a} \cdot \mathbf{c}}{[\mathbf{a} \ \mathbf{b} \ \mathbf{c}]}$$

...(vi)

On substituting these values in Eq. (i), we get

$$\mathbf{a} = \frac{\mathbf{a} \cdot \mathbf{a}}{[\mathbf{a} \mathbf{b} \mathbf{c}]} (\mathbf{b} \times \mathbf{c}) + \frac{\mathbf{a} \cdot \mathbf{b}}{[\mathbf{a} \mathbf{b} \mathbf{c}]} (\mathbf{c} \times \mathbf{a}) + \frac{\mathbf{a} \cdot \mathbf{c}}{[\mathbf{a} \mathbf{b} \mathbf{c}]} (\mathbf{a} \times \mathbf{b})$$
or 
$$\mathbf{a} = \frac{1}{[\mathbf{a} \mathbf{b} \mathbf{c}]} \{ \mathbf{a} \cdot \mathbf{a} (\mathbf{b} \times \mathbf{c}) + \mathbf{a} \cdot \mathbf{b} (\mathbf{c} \times \mathbf{a}) + \mathbf{a} \cdot \mathbf{c} (\mathbf{a} \times \mathbf{b}) \}$$

**134.** Let

**Solutions** (Q.Nos. 137 to 139)

We have  $|\mathbf{x}| = |\mathbf{y}| = |\mathbf{z}| = \sqrt{2}$  and  $\mathbf{x}$ ,  $\mathbf{y}$ ,  $\mathbf{z}$  make angle of 60° with each other.

$$\therefore \mathbf{x} \cdot \mathbf{y} = |\mathbf{x}| |\mathbf{y}| \cos 60^{\circ} = \sqrt{2}(\sqrt{2}) \cdot \frac{1}{2} = 1$$
$$\mathbf{y} \cdot \mathbf{z} = |\mathbf{y}| |\mathbf{z}| \cos 60^{\circ} = \sqrt{2}(\sqrt{2}) \left(\frac{1}{2}\right) = 1$$

and 
$$\mathbf{x} \cdot \mathbf{z} = |\mathbf{x}| |\mathbf{z}| \cos 60^{\circ} = \sqrt{2}(\sqrt{2}) \left(\frac{1}{2}\right) = 1$$
  
$$\mathbf{x} \cdot \mathbf{x} = |\mathbf{x}|^2 = 2$$

$$\mathbf{y} \cdot \mathbf{y} = |\mathbf{y}|^2 = 2$$
 and  $\mathbf{z} \cdot \mathbf{z} = |z|^2 = 2$ 

Now, 
$$\mathbf{x} \times (\mathbf{y} \times \mathbf{z}) = \mathbf{a}$$
 and  $\mathbf{y} \times (\mathbf{z} \times \mathbf{x}) = \mathbf{b}$  (given)

$$\Rightarrow$$
  $(\mathbf{x} \cdot \mathbf{z}) \mathbf{y} - (\mathbf{x} \cdot \mathbf{y})\mathbf{z} = \mathbf{a} \text{ and } (\mathbf{y} \cdot \mathbf{x})\mathbf{z} - (\mathbf{y} \cdot \mathbf{z})\mathbf{x} = \mathbf{b}$ 

$$\Rightarrow$$
  $y - z = a$  and  $z - x = b$ 

$$\Rightarrow$$
  $y - x = a + b$ 

Thus, we have

$$\mathbf{y} - \mathbf{z} = \mathbf{a} \qquad \qquad \dots (i)$$

$$\mathbf{z} - \mathbf{x} = \mathbf{b} \qquad \qquad \dots (ii)$$

$$\mathbf{y} - \mathbf{x} = \mathbf{a} + \mathbf{b} \qquad \qquad \dots (iii)$$

Now, 
$$\mathbf{x} \times \mathbf{y} = \mathbf{c}$$
 (given)

$$\Rightarrow \qquad \mathbf{x} \times (\mathbf{x} \times \mathbf{y}) = \mathbf{x} \times \mathbf{c} \text{ (taking cross-product with } \mathbf{x})$$

$$\Rightarrow (\mathbf{x} \cdot \mathbf{y}) \times \mathbf{x} - (\mathbf{x} \cdot \mathbf{x})\mathbf{y} = \mathbf{x} \times \mathbf{c}$$

$$\Rightarrow \qquad \mathbf{x} - 2\mathbf{y} = \mathbf{x} \times \mathbf{c} \qquad \dots \text{(iv)}$$

Again, 
$$\mathbf{x} \times \mathbf{y} = \mathbf{c}$$

$$\Rightarrow$$
  $y \times (x \times y) = y \times c$  (taking cross product with y)

$$\Rightarrow (\mathbf{y} \cdot \mathbf{y})\mathbf{x} - (\mathbf{y} \cdot \mathbf{x})\mathbf{y} = \mathbf{y} \times \mathbf{c}$$

$$\Rightarrow 2\mathbf{x} - \mathbf{y} = \mathbf{y} \times \mathbf{c} \qquad \dots \text{(iv)}$$

On subtracting Eqs. (iv) and (v), we get

$$\mathbf{x} - \mathbf{y} = (\mathbf{y} \times \mathbf{c}) - (\mathbf{x} \times \mathbf{c})$$

$$\Rightarrow \qquad \mathbf{x} \times \mathbf{y} = (\mathbf{y} - \mathbf{x}) \times \mathbf{c}$$

 $\mathbf{x} + \mathbf{y} = (\mathbf{a} + \mathbf{b}) \times \mathbf{c}$ 

Adding Eqs. (iii) and (vi), we get

$$2y = (a + b) + (a + b) \times c, y = \frac{1}{2}[(a + b)(a + b) \times c]$$

Substituting the value of  $\mathbf{y}$  in Eq. (iii) in Eq. (i), we get

$$\mathbf{x} = \frac{1}{2}[(\mathbf{a} + \mathbf{b}) + (\mathbf{a} + \mathbf{b}) \times \mathbf{c}] - (\mathbf{a} + \mathbf{b})$$

$$\Rightarrow \qquad \mathbf{x} = \frac{1}{2}[(\mathbf{a} + \mathbf{b}) \times \mathbf{c} - (\mathbf{a} + \mathbf{b})]$$

$$\mathbf{z} = \frac{1}{2}[(\mathbf{a} + \mathbf{b}) + (\mathbf{a} + \mathbf{b}) \times \mathbf{c}] - \mathbf{a}$$

$$\mathbf{z} = \frac{1}{2}[(\mathbf{b} - \mathbf{a}) + (\mathbf{a} + \mathbf{b}) \times \mathbf{c}].$$

We have,

Equation of the line *CP*,  $\mathbf{r} = \mathbf{c} + \lambda_2 \left( \frac{\mathbf{b}}{3} - \mathbf{c} \right)$ 

*R* is the point of intersection of *AQ* and *CP*.

 $\Rightarrow$  For point R, we have

$$\lambda_1 \left( \frac{2\mathbf{b} + \mathbf{c}}{3} \right) = \mathbf{c} + \lambda_2 \left( \frac{\mathbf{b}}{3} - \mathbf{c} \right)$$

 $\Rightarrow \frac{2\lambda_2}{3} = \frac{\lambda_2}{3}$  (comparing coefficients of **b** and **c**)

and

$$\frac{\lambda_1}{3} = 1 - \lambda_2$$

On solving, we get

$$\lambda_1 = 3/7, \lambda_2 = 6/7$$

Now,

 $RC = c - \frac{1}{7} (2b + c) = \frac{(6c - 2b)}{7}$

$$= \frac{1}{49} (30\mathbf{b} \times \mathbf{c} + 2\mathbf{c} \times \mathbf{b}) = \frac{28}{49} (\mathbf{b} \times \mathbf{c})$$

 Area of  $\triangle ABC = \frac{49}{28}$  sq units.

Since, the mid-point  $\frac{\mathbf{a} + \mathbf{c}}{2}$  of **AC** lies on **OB**, there exits a

Area of

On multiplying both sides with **b**, we have

This moment is equal to sum of the moments  $MA \times F_1$  and  $MB \times F_2$  of component forces (the cross product of vectors is distributive.)

Since,

and 
$$\mathbf{b} = \hat{\mathbf{i}} + \hat{\mathbf{j}} \Rightarrow |\mathbf{b}| = \sqrt{1+1} = \sqrt{2}$$

Now, 
$$|\mathbf{c} - \mathbf{a}| = 3 \Rightarrow |\mathbf{c} - \mathbf{a}|^2 = 9$$

$$\Rightarrow \qquad (\mathbf{c} - \mathbf{a}) \cdot (\mathbf{c} - \mathbf{a}) = 9$$

$$\Rightarrow |\mathbf{c}|^2 + |\mathbf{a}|^2 - 2\mathbf{c} \cdot \mathbf{a} = 9$$

$$|\mathbf{a} \times \mathbf{b}| \times \mathbf{c}| = 3$$

$$\Rightarrow |\mathbf{a} \times \mathbf{b}| |\mathbf{c}| \sin 30^{\circ} = 3 \Rightarrow |\mathbf{c}| = \frac{6}{|\mathbf{a} \times \mathbf{b}|}$$

But 
$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & 1 & -2 \\ 1 & 1 & 0 \end{vmatrix} = 2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$$

$$\therefore \qquad |\mathbf{c}| \frac{6}{\sqrt{2}} = 2 \qquad \dots \text{(ii)}$$

From Eqs. (i) and (ii), we get

$$(2)^{2} + (3)^{2} - 2\mathbf{c} \cdot \mathbf{a} = 9 \implies 4 + 9 - 2\mathbf{c} \cdot \mathbf{a} = 9 \implies \mathbf{c} \cdot \mathbf{a} = 2$$

and 
$$[\mathbf{a} \ \mathbf{a} \ \mathbf{b}] = [\mathbf{a} \ \mathbf{b} \ \mathbf{b}] = [\mathbf{a} \ \mathbf{c} \ \mathbf{c}] = 0$$

Further, simplify it and get the result.

Now, 
$$[\mathbf{a} \times \mathbf{b} \ \mathbf{b} \times \mathbf{c} \ \mathbf{c} \times \mathbf{a}]$$
  
 $= \mathbf{a} \times \mathbf{b} \cdot ((\mathbf{b} \times \mathbf{c}) \times (\mathbf{c} \times \mathbf{a}))$

 $= [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2$  {::  $[\mathbf{a} \ \mathbf{b} \ \mathbf{c}] = [\mathbf{b} \ \mathbf{c} \ \mathbf{a}]$ }

Hence,  $[\mathbf{a} \times \mathbf{b} \ \mathbf{b} \times \mathbf{c} \ \mathbf{c} \times \mathbf{a}] = \lambda [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]^2$

# **Session 1**

# Introduction, Position Vector of a Point in Space, Shifting of Origin, Distance Formula, Section Formula, Direction Cosines and Direction Ratios of a Vector, Projection of the Line Segment Joining Two Points on a Given Line

#### Introduction

Let OY and OZ be two perpendicular lines which intersect at O and let a third straight line OX be perpendicular to the plane in which they lie. The three mutually perpendicular lines form a set of coordinate axis. They determine three mutually perpendicular planes called coordinate planes.

#### Remarks

- The axes to coordinate form a right handed set (in the figure) i.e. a right handed screw, driven from O to X would rotate in the sense from OY to OZ.
- 2. The points A B and C are the orthogonal projections of P on the X, Y and Z-axes.
- **3.** Points *L*, *M* and *N* are (*x*, 0, *z*), (*x*, *y*, 0), (0, *y*, *z*) and *A*, *B* and *C* are (*x*, 0, 0), (0, *y*, 0), (0, 0, *z*), respectively.

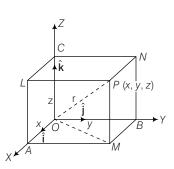

# Position Vector of a Point in Space

Let  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$ ,  $\hat{\mathbf{k}}$  be unit vector (called base vector) along OX, OY and OZ, respectively.

Let P(x, y, z) be a point in space, let the position of P be **r**.

Then, 
$$\mathbf{r} = \mathbf{OP} = \mathbf{OM} + \mathbf{MP}$$
$$= (\mathbf{OA} + \mathbf{AM}) + \mathbf{MP} = \mathbf{OA} + \mathbf{OB} + \mathbf{OC}$$
$$\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$$

Thus, the position vector of a point *P* is,  $x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$ .

Any point on 
$$X-axis = (x, 0, 0)$$

$$Y-axis = (0, y, 0)$$

$$Z-axis = (0, 0, z)$$

$$XY-plane = (x, y, 0)$$

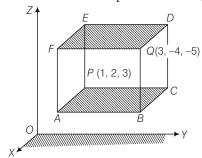

$$YZ-plane = (0, y, z)$$

$$ZX-plane = (x, 0, z)$$

$$OP = \sqrt{x^2 + y^2 + z^2}$$

**Example 1.** Planes are drawn parallel to the coordinate planes through the points (1,2,3) and (3,-4,-5). Find the lengths of the edges of the parallelopiped so formed.

**Sol.** Let P = (1, 2, 3), Q = (3, -4, -5) through which planes are drawn parallel to the coordinate planes shown as,

 $\therefore PE$  = Distance between parallel planes *ABCP* and *FQDE*, i.e. (along Z-axis)

$$= |-5-3| = 8$$

PA = Distance between parallel planes ABQF and PCDE, i.e. (along X-axis)

$$= |3 - 1| = 2$$

PC = Distance between parallel planes BCDQ and APEF, i.e. (along Y-axis)

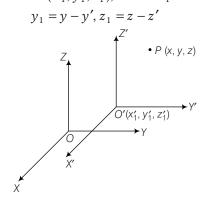

$$= |-4-2| = 6$$

:. Lengths of edges of the parallelopiped are 2, 6, 8.

## **Shifting of Origin**

Shifting the origin to another point without changing the directions of the axes is called the translation of axes.

Let the origin O(0, 0, 0) be shifted to another point O'(x', y', z') without changing the direction of axes. Let the new coordinate frame be O'X'Y'Z'. Let P(x, y, z) be a point with respect to the coordinate frame *OXYZ*. Then, coordinate of point P with respect to new coordinate frame O'X'Y'Z' is  $(x_1, y_1, z_1)$ , where  $x_1 = x - x'$ ,

**Example 2.** If the origin is shifted (1, 2, -3) without changing the directions of the axis, then find the new coordinates of the point (0, 4, 5) with respect to new

**Sol.** In the new frame  $x' = x - x_1$ ,  $y' = y - y_1$ ,  $z' = z - z_1$ , where  $(x_1, y_1, z_1)$  is shifted origin.

$$\Rightarrow x' = 0 - 1 = -1, y' = 4 - 2 = 2, z' = 5 + 3 = 8$$

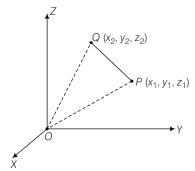

Hence, the coordinates of the point with respect to the new coordinates frame are (-1, 2, 8).

#### **Distance Formula**

The distance between the points  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  is given by

$$PQ = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

**Proof.** Let *O* be the origin and let  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  be two given points.

The, 
$$\mathbf{OP} = x_1 \hat{\mathbf{i}} + y_1 \hat{\mathbf{j}} + z_1 \hat{\mathbf{k}}$$
  
 $\mathbf{OQ} = x_2 \hat{\mathbf{i}} + y_2 \hat{\mathbf{j}} + z_2 \hat{\mathbf{k}}$ 

Now, **PQ** = Position vector of Q – Position vector of P

= OQ - OP  
= 
$$(x_2 \hat{\mathbf{i}} + y_2 \hat{\mathbf{j}} + z_2 \hat{\mathbf{k}}) - (x_1 \hat{\mathbf{i}} + y_2 \hat{\mathbf{j}} + z_1 \hat{\mathbf{k}})$$
  
=  $(x_2 - x_1)\hat{\mathbf{i}} + (y_2 - y_1)\hat{\mathbf{j}} + (z_2 - z_1)\hat{\mathbf{k}}$ 

$$PQ = | \mathbf{PQ} |$$

$$= \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$
Hence,  $PQ = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$ 

**Example 3.** Find the distance between the points P(-2,4,1) and Q(1,2,-5).

**Sol.** We have, 
$$PQ = \sqrt{(1+2)^2 + (2-4)^2 + (-5-1)^2}$$
  
 $PQ = \sqrt{3^2 + (-2)^2 + (-6)^2}$   
 $= \sqrt{9+4+36}$   
 $= \sqrt{49} = 7$ 

**Example 4.** Prove by using distance formula that the points P(1, 2, 3), Q(-1, -1, -1) and R(3, 5, 7) are collinear.

Sol. We have,

$$PQ = \sqrt{(-1-1)^2 + (-1-2)^2 + (-1-3)^2}$$

$$= \sqrt{4+9+16} = \sqrt{29}$$

$$QR = \sqrt{(3+1)^2 + (5+1)^2 + (7+1)^2}$$

$$= \sqrt{16+36+64}$$

$$= \sqrt{116} = 2\sqrt{29}$$
and
$$PR = \sqrt{(3-1)^2 + (5-2)^2 + (7-3)^2}$$

$$= \sqrt{4+9+16} = \sqrt{29}$$

QR = QP + PRSince,

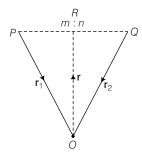

Therefore, the given points are collinear.

#### **Section Formula**

#### 1. Section Formula for Internal Division

Let P and Q be two points whose position vectors are  $\mathbf{r}_1$  and  $\mathbf{r}_2$  respectively. Let R be a point on PQ dividing it in the ratio m:n. Then, the position vector of R is given by

$$\mathbf{r} = \frac{m\mathbf{r}_2 + n\mathbf{r}_1}{m + n}$$

**Proof.** Let *O* be the origin. Then,  $\mathbf{OP} = \mathbf{r}_1$ ,  $\mathbf{OQ} = \mathbf{r}_2$  and  $\mathbf{OR} = \mathbf{r}$ 

Now, 
$$\frac{PR}{RQ} = \frac{m}{n}$$

$$\Rightarrow nPR = mRQ$$

$$\Rightarrow n(OR - OP) = m(OQ - OR)$$

$$\Rightarrow n(\mathbf{r} - \mathbf{r}_1) = m(\mathbf{r}_2 - \mathbf{r})$$

$$\Rightarrow (m+n)\mathbf{r} = m\mathbf{r}_2 + n\mathbf{r}_1$$

$$\Rightarrow \mathbf{r} = \frac{m\mathbf{r}_2 + n\mathbf{r}_1}{m+n}$$

#### Corollary

**Mid-point formula** Let P and Q be two points whose position vectors are given by  $\mathbf{r}_1$  and  $\mathbf{r}_2$  respectively. Then, the position vector of the mid-point R of PQ is given by,

$$\mathbf{r} = \frac{\mathbf{r}_1 + \mathbf{r}_2}{2}.$$

#### 2. Section Formula for External Division

Let P and Q be the points whose position vectors are  $\mathbf{r}_1$  and  $\mathbf{r}_2$  respectively. Let R be a point on PQ dividing it externally in the ratio m:n. Then, the position vector of R is given by,

$$\mathbf{r} = \frac{m\mathbf{r}_2 - n\mathbf{r}_1}{m - n}$$

**Proof.** Let *O* be the origin. Then,  $\mathbf{OP} = \mathbf{r}_1$ ,  $\mathbf{OQ} = \mathbf{r}_2$  and  $\mathbf{OR} = \mathbf{r}$ 

Now, 
$$\frac{PR}{QR} = \frac{m}{n}$$

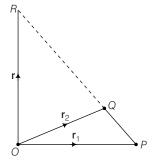

$$\Rightarrow nPR = mQR$$

$$\Rightarrow n(OR - OP) = m(OR - OQ)$$

$$\Rightarrow n(\mathbf{r} - \mathbf{r}_1) = m(\mathbf{r} - \mathbf{r}_2)$$

$$\Rightarrow (m - n)\mathbf{r} = m\mathbf{r}_2 - n\mathbf{r}_1$$

$$\Rightarrow \mathbf{r} = \left(\frac{m\mathbf{r}_2 - n\mathbf{r}_1}{m - n}\right)$$

**Corollary 1.** If R(x, y, z) is a point dividing the join of  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  in the ratio m : n.

Then, 
$$x = \frac{mx_2 + nx_1}{m+n}$$
,  $y = \frac{my_2 + ny_1}{m+n}$ ,  $z = \frac{mz_2 + nz_1}{m+n}$ 

**Corollary 2.** The coordinates of the mid-point of the joint of  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  are

of 
$$P(x_1, y_1, z_1)$$
 and  $Q(x_2, y_2, z_2)$  are  $\left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}, \frac{z_1 + z_2}{2}\right)$ 

**Corollary 3.** The coordinates of a point R which divides the join of  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  externally in the ratio m:n are

$$\left(\frac{mx_2-nx_1}{m-n},\frac{my_2-ny_1}{m-n},\frac{mz_2-nz_1}{m-n}\right)$$

**Corollary 4.** The coordinate of centroid of triangle with vertices  $(x_1, y_1, z_1), (x_2, y_2, z_2), (x_3, y_3, z_3)$  is

$$\left(\frac{x_1+x_2+x_3}{3}, \frac{y_1+y_2+y_3}{3}, \frac{z_1+z_2+z_3}{3}\right)$$

**Corollary 5.** Centroid of tetrahedron with vertices  $(x_1, y_1, z_1), (x_2, y_2, z_2), (x_3, y_3, z_3), (x_4, y_4, z_4)$  is  $\left(\frac{x_1 + x_2 + x_3 + x_4}{4}, \frac{y_1 + y_2 + y_3 + y_4}{4}, \frac{z_1 + z_2 + z_3 + z_4}{4}\right)$ 

$$\left(\frac{z_1 + z_2 + z_3 + z_4}{4}\right)$$

**Example 5.** Find the ratio in which 2x + 3y + 5z = 1 divides the line joining the points (1, 0, -3) and (1, -5, 7).

**Sol.** Let 2x + 3y + 5z = 1 divides (1, 0, -3) and (1, -5, 7) in the ratio of k : 1 at point P.

$$\Rightarrow 2\left(\frac{k+1}{k+1}\right) + 3\left(\frac{-5k}{k+1}\right) + 5\left(\frac{7k-3}{k+1}\right) = 1$$

$$\Rightarrow \qquad 21k = 14 \implies k = \frac{2}{3}$$

 $\therefore 2x + 3y + 5z = 1$ , divides (1, 0, -3) and (1, -5, 7) in the ratio

**Example 6.** If A(3, 2, -4), B(5, 4, -6) and C(9, 8, -10)are three collinear points, then find the ratio in which point C divides AB.

**Sol.** Let *C* divide *AB* in the ratio  $\lambda$  : 1. Then,

$$C \equiv \left(\frac{5\lambda + 3}{\lambda + 1}, \frac{4\lambda + 2}{\lambda + 1}, \frac{-6\lambda - 4}{\lambda + 1}\right) = (9, 8, -10)$$

Comparing,  $5\lambda + 3 = 9\lambda + 9$  or  $4\lambda = -6$ 

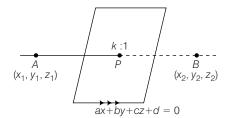

$$\lambda = -\frac{3}{2}$$

Also, from  $4\lambda + 2 = 8\lambda + 8$  and  $-6\lambda - 4 = -10\lambda - 10$ , we get the same value of  $\lambda$ .

 $\therefore$  *C* divides *AB* in the ratio 3 : 2 externally.

**Example 7.** Show that the plane ax + by + cz + d = 0divides the line joining  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  in the ratio of  $\left(-\frac{ax_1 + ay_1 + cz_1 + d}{ax_2 + by_2 + cz_2 + d}\right)$ .

**Sol.** Let the plane ax + by + cz + d = 0 divides the line joining  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  in the ratio k : 1 as shown in

$$\therefore \text{ Coordinates of } P\left(\frac{kx_2 + x_1}{k+1}, \frac{ky_2 + y_1}{k+1}, \frac{kz_2 + z_1}{k+1}\right)$$

i.e., 
$$a\left(\frac{kx_2 + x_1}{k+1}\right) + b\left(\frac{ky_2 + y_1}{k+1}\right) + c\left(\frac{kz_2 + z_1}{k+1}\right) + d = 0$$

$$\Rightarrow a(kx_2 + x_1) + b(ky_2 + y_1) + c(kz_2 + z_1) + d(k+1) = 0$$

$$\Rightarrow k(ax_2 + by_2 + cz_2 + d) + (ax_1 + by_1 + cz_1 + d) =$$

$$\Rightarrow k(ax_2 + by_2 + cz_2 + d) + (ax_1 + by_1 + cz_1 + d) = 0$$

$$\Rightarrow k = -\frac{(ax_1 + by_1 + cz_1 + d)}{(ax_2 + by_2 + cz_2 + d)}$$

#### Remark

Students are advised to learn above result as a formula i.e. ax + by + cz + d = 0 divides join of  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  in ratio of  $-\frac{(ax_1 + by_1 + cz_1 + d)}{(ax_2 + by_2 + cz_2 + d)}$ .

**Example 8.** Find the ratio in which the join of (2, 1, 5), (3, 4, 3) is divided by the plane 2x + 2y - 2z - 1 = 0.

**Sol.** Using above result,

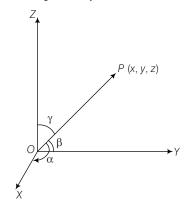

Required ratio = 
$$\frac{\{(2 (2) + 2 (1) - 2 (5) - 1\}}{\{2 (3) + 2 (4) - 2 (3) - 1\}}$$
$$= \frac{\{6 - 11\}}{\{14 - 7\}} = \frac{-5}{7}$$

 $\Rightarrow$  2x + 2y - 2z - 1 = 0 divides (2,1,5) and (3, 4, 5) externally in ratio of 5:7.

### **Direction Cosines and Direction Ratios of a Vector**

#### 1. Direction Cosines [DC's]

If  $\alpha$ ,  $\beta$  and  $\gamma$  are the angles which a vector **OP** makes with the positive directions of the coordinate axes OX, OY and OZ respectively. Then cos α, cos β and cos γ are known as direction cosines of **OP** and are generally denoted by letters *l*, *m* and *n*, respectively.

Thus,  $l = \cos \alpha$ ;  $m = \cos \beta$ ;  $n = \cos \gamma$ . The angles  $\alpha$ ,  $\beta$  and  $\gamma$ are known as direction angles and they satisfy the condition  $0 \le \alpha$ ,  $\beta$ ,  $\gamma \le \pi$ .

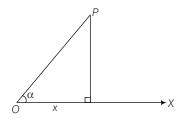

It can be seen form the figure

$$\cos \alpha = \frac{x}{OP}$$

Similarly,

$$\cos \beta = \frac{y}{OP}$$

$$\cos \gamma = \frac{z}{OP}$$

Where, *OP* is the modulus of positive vector of *P*.

Clearly, 
$$OP = \sqrt{x^2 + y^2 + z^2}$$

So, 
$$l^2 + m^2 + n^2 = \cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma$$
  
=  $\frac{x^2 + y^2 + z^2}{OP^2} = \frac{x^2 + y^2 + z^2}{x^2 + y^2 + z^2} = 1$ 

$$\therefore l^2 + m^2 + n^2 = \cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$$

$$\therefore \text{ If } \qquad \mathbf{OP} = \mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$$
Then, 
$$\hat{\mathbf{r}} = l\hat{\mathbf{i}} + m\hat{\mathbf{j}} + n\hat{\mathbf{k}}$$

By definition it follows that the direction cosine of the axis x are  $\cos 0^{\circ}$ ,  $\cos 90^{\circ}$ ,  $\cos 90^{\circ}$ , i.e. (1, 0, 0).

Similarly, direction cosine of the axes Y and Z are (0, 1, 0) and (0, 0, 1), respectively.

#### 2. **Direction Ratios** (DR's)

Let l, m and n be the direction cosines of a vector  $\mathbf{r}$  and a, b and c be three numbers such that a, b and c are proportional to l, m and n

i.e. 
$$\frac{l}{a} = \frac{m}{b} = \frac{n}{c} = k$$
or 
$$(l, m, n) = (ka, kb, kc)$$

 $\Rightarrow$  (a, b, c) are direction ratios.

If 
$$\left(\frac{1}{\sqrt{3}}, \frac{-1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right)$$
 are direction cosines of a vector  $\mathbf{r}$ , then

its direction ratios are (1, -1, 1) or (-1, 1, -1) or (2, -2, 2) or  $(\lambda, -\lambda, \lambda)$ ... etc.

It is evident from the above definition that to obtain direction ratios of a vector from its direction cosines, we just multiply them by a common number.

"That shows there can be infinitely many direction ratios for a given vector but the direction cosines are unique".

To obtain direction cosines from direction ratios.

Let a, b and c be direction ratios of a vector  $\mathbf{r}$  having direction cosines l, m and n. Then,

$$l = \lambda a, m = \lambda b, n = \lambda c$$
 (by definition)  

$$\vdots \qquad \qquad l^2 + m^2 + n^2 = 1$$

$$\Rightarrow \qquad \qquad a^2 \lambda^2 + b^2 \lambda^2 + c^2 \lambda^2 = 1$$

$$\Rightarrow \qquad \lambda = \pm \frac{1}{\sqrt{a^2 + b^2 + c^2}}$$
So,
$$l = \pm \frac{a}{\sqrt{a^2 + b^2 + c^2}},$$

$$m = \pm \frac{b}{\sqrt{a^2 + b^2 + c^2}},$$

$$n = \pm \frac{c}{\sqrt{a^2 + b^2 + c^2}}$$

For example, let the direction ratios of a point be (3, 1, -2).  $\Rightarrow$  Direction cosines are

$$\left(\frac{3}{\sqrt{3^2+1^2+(-2)^2}}, \frac{1}{\sqrt{3^2+1^2+(-2)^2}}, \frac{-2}{\sqrt{3^2+1^2+(-2)^2}}\right) \\
\Rightarrow \left(\frac{3}{\sqrt{14}}, \frac{1}{\sqrt{14}}, -\frac{2}{\sqrt{14}}\right)$$

# 3. Angle between Two Vectors in Terms of Direction Cosines and Direction Ratios

Let **a** and **b** be two given vectors with direction cosines  $l_1$ ,  $m_1$ ,  $n_1$  and  $l_2$ ,  $m_2$ ,  $n_2$  respectively. Then,

$$\mathbf{a} = l_1 \hat{\mathbf{i}} + m_1 \hat{\mathbf{j}} + n_1 \hat{\mathbf{k}}$$
 and  $\mathbf{b} = l_2 \hat{\mathbf{i}} + m_2 \hat{\mathbf{j}} + n_2 \hat{\mathbf{k}}$ 

 $\therefore \cos \theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}| \cdot |\mathbf{b}|}, \text{ where } \theta \text{ be the angle between } \mathbf{a} \text{ and } \mathbf{b}.$ 

$$\Rightarrow \qquad \cos \theta = \frac{|l_1 \hat{\mathbf{i}} + m_1 \hat{\mathbf{j}} + n_1 \hat{\mathbf{k}}| \cdot |l_2 \hat{\mathbf{i}} + m_2 \hat{\mathbf{j}} + n_2 \hat{\mathbf{k}}|}{|l_1 \hat{\mathbf{i}} + m_1 \hat{\mathbf{j}} + n_1 \hat{\mathbf{k}}| |l_2 \hat{\mathbf{i}} + m_2 \hat{\mathbf{j}} + n_2 \hat{\mathbf{k}}|}$$

$$\Rightarrow \qquad \cos \theta = \frac{l_1 l_2 + m_1 m_2 + n_1 n_2}{\sqrt{l_1^2 + m_1^2 + n_1^2} \sqrt{l_2^2 + m_2^2 + n_2^2}}$$

$$\Rightarrow \cos \theta = l_1 l_2 + m_1 m_2 + n_1 n_2 \qquad [\because l^2 + m^2 + n^2 = 1]$$

Also, 
$$\sin^2 \theta = 1 - \cos^2 \theta$$

$$= (l_1^2 + m_1^2 + n_1^2)(l_1^2 + m_2^2 + n_2^2)$$

$$-(l_1l_2 + m_1m_2 + n_1n_2)^2$$

$$\Rightarrow \sin^2 \theta = (m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2 + (l_1 m_2 - l_2 m_1)^2$$

$$\Rightarrow \sin \theta = \pm \sqrt{\frac{(m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2}{+ (l_1 m_2 - l_2 m_1)^2}}$$

#### Remarks

**1.** Acute angle  $\theta$  between the two lines having direction cosines  $l_1$ ,  $m_1$ ,  $n_1$  and  $l_2$ ,  $m_2$ ,  $n_2$  is given by

$$\cos \theta = | l_1/2 + m_1 m_2 + n_1 n_2 |$$
  

$$\sin \theta = \sqrt{(l_1 m_2 - l_2 m_1)^2 + (m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2}$$

**2.** If  $a_1$ ,  $b_1$ ,  $c_1$  and  $a_2$ ,  $b_2$ ,  $c_2$  are the direction ratios of two lines, then the acute angle  $\theta$  between them is given by

$$\cos \theta = \frac{\begin{vmatrix} a_1 a_2 + b_1 b_2 + c_1 c_2 \end{vmatrix}}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}}$$
$$\sin \theta = \frac{\begin{vmatrix} (a_1 b_2 - a_2 b_1)^2 + (b_1 c_2 - b_2 c_1)^2 \\ + (c_1 a_2 - c_2 a_1)^2 \end{vmatrix}}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}}$$

**3.** The two lines with direction cosines  $l_1$ ,  $m_1$ ,  $n_1$  and  $I_2$ ,  $m_2$ ,  $n_2$  are perpendicular to each other if  $\theta = \frac{\pi}{2}$ 

 $\cos \theta = l_1 l_2 + m_1 m_2 + n_1 n_2 = 0$ 

**4.** The two lines with direction cosines  $l_1$ ,  $m_1$ ,  $n_1$  and  $l_2$ ,  $m_2$ ,  $n_2$  are parallel to each other if  $\theta = 0$ 

or 
$$\pi \Rightarrow \sin \theta = 0$$
  

$$\Rightarrow (m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2 + (l_1 m_2 - l_2 m_1)^2 = 0$$

$$\Rightarrow \frac{l_1}{l_2} = \frac{m_1}{m_2} = \frac{n_1}{n_2}$$

**5.** The angle between two lines having direction ratios  $a_1$ ,  $b_1$ ,  $c_1$ and  $a_2$ ,  $b_2$ ,  $c_2$  is given by

$$\cos \theta = \frac{a_1 a_2 + b_1 b_2 + c_1 c_2}{\sqrt{(a_1^2 + b_1^2 + c_1^2 \sqrt{a_2^2 + b_2^2 + c_2^2})}}$$

Thus, the two straight lines are perpendicular, if

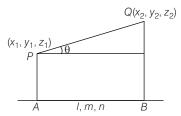

$$a_1a_2 + b_1b_2 + c_1c_2 = 0$$

The two straight lines are parallel if  $\frac{a_1}{a_2} = \frac{b_1}{b_2} = \frac{c_1}{c_2}$ 

## **Projection of the Line Segment** Joining Two Points on a Given Line

The projection of the line segment joining two given points  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  on the line having direction cosines l, m, n is given by

 $l(x_2 - x_1) + m(y_2 - y_1) + n(z_2 - z_1)$ , which is clear from the vector.

 $\mathbf{PQ} = (x_2 - x_1)\hat{\mathbf{i}} + (y_2 - y_1)\hat{\mathbf{j}} + (z_2 - z_1)\hat{\mathbf{k}}$ and the line  $\mathbf{AB} = l\hat{\mathbf{i}} + m\hat{\mathbf{j}} + n\hat{\mathbf{k}}$ 

The projection of PO on AB

$$= \frac{\mathbf{PQ} \cdot \mathbf{AB}}{|\mathbf{AB}|} = \frac{l(x_2 - x_1) + m(y_2 - y_1) + n(z_2 - z_1)}{\sqrt{l^2 + m^2 + n^2}}$$
$$= l(x_2 - x_1) + m(y_2 - y_1) + n(z_2 - z_1)$$

**Example 9.** What are the direction cosines of a line which is equally inclined to the coordinate axes?

**Sol.** If  $\alpha$ ,  $\beta$  and  $\gamma$  are the angles that a line makes with the coordinate axes, then if they are equally inclined.

$$\Rightarrow \qquad \alpha = \beta = \gamma$$
Also, 
$$l^2 + m^2 + n^2 = 1$$

$$\Rightarrow \qquad \cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$$

$$\Rightarrow \qquad \cos^2 \alpha + \cos^2 \alpha + \cos^2 \alpha = 1$$

$$\Rightarrow \qquad 3\cos^2 \alpha = 1$$

$$\Rightarrow \qquad \cos \alpha = \pm \frac{1}{\sqrt{3}} = \cos \beta = \cos \gamma$$

$$\therefore \text{ Direction cosines are } \left(\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right)$$
or
$$\left(-\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}}\right)$$

**Example 10.** If a line makes angles  $\alpha$ ,  $\beta$  and  $\gamma$  with the coordinates axes, prove that  $\sin^2 \alpha + \sin^2 \beta + \sin^2 \gamma = 2$ .

**Sol.** Let *l*, *m* and *n* be the direction cosines of the given vector.

Then,  $l = \cos \alpha$ ,  $m = \cos \beta$ ,  $n = \cos \gamma$  $l^2 + m^2 + n^2 = 1$  $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$  $1 - \sin^2 \alpha + 1 - \sin^2 \beta + 1 - \sin^2 \gamma = 1$  $\sin^2 \alpha + \sin^2 \beta + \sin^2 \gamma = 2$ 

**Example 11.** A line OP through origin O is inclined at 30° and 45° to OX and OY, respectively. Find the angle at which it is inclined to OZ.

**Sol.** Let l, m and n be the direction cosines of the given vector.

where, 
$$\alpha = 30^{\circ}, \beta = 45^{\circ}$$

$$\therefore \qquad \cos^{2} \alpha + \cos^{2} \beta + \cos^{2} \gamma = 1$$

$$\Rightarrow \qquad \cos^{2} 30^{\circ} + \cos^{2} 45^{\circ} + \cos^{2} \gamma = 1$$

$$\Rightarrow \qquad \left(\frac{\sqrt{3}}{2}\right)^{2} + \left(\frac{1}{\sqrt{2}}\right)^{2} + \cos^{2} \gamma = 1$$

$$\Rightarrow \qquad \cos^{2} \gamma = 1 - \frac{3}{4} - \frac{1}{2}$$

$$\Rightarrow \qquad \cos^{2} \gamma = \frac{4 - 3 - 2}{4}$$

$$\Rightarrow \qquad \cos^{2} \gamma = -\frac{1}{4} \text{ which is not possible.}$$

 $\therefore$  There exists no point which is inclined to 30° to X-axis and  $45^{\circ}$  to Y-axis.

- **Example 12.** Find the direction cosines of a vector  $\mathbf{r}$  which is equally inclined to OX, OY and OZ. If  $|\mathbf{r}|$  is given, find the total number of such vectors.
- **Sol.** Let l, m and n be the direction cosines of  $\mathbf{r}$ .

Since,  $\mathbf{r}$  is equally inclined with X, Y and Z-axes.

$$l^2 + m^2 + n^2 = 1$$

$$\Rightarrow$$
  $3l^2 = 1$ 

(:: l = m = n)

$$\Rightarrow$$

$$l=\pm\frac{1}{\sqrt{3}}$$

∴ Direction cosines of **r** are  $\pm \frac{1}{\sqrt{3}}$ ,  $\pm \frac{1}{\sqrt{3}}$ ,  $\pm \frac{1}{\sqrt{3}}$ .

Now,  $\mathbf{r} = |\mathbf{r}| (l\,\hat{\mathbf{i}} +$ 

$$\mathbf{r} = |\mathbf{r}|(l\,\hat{\mathbf{i}} + m\,\hat{\mathbf{j}} + n\,\hat{\mathbf{k}})$$

$$\Rightarrow \qquad \qquad \mathbf{r} = \mid \mathbf{r} \mid \left( \pm \frac{1}{\sqrt{3}} \; \hat{\mathbf{i}} \; \pm \frac{1}{\sqrt{3}} \; \hat{\mathbf{j}} \; \pm \frac{1}{\sqrt{3}} \; \hat{\mathbf{k}} \right)$$

Since, '+' and '-' signs can be arranged at three planes.

There are eight vectors (i.e.  $2 \times 2 \times 2$ ) which are equally inclined to axes.

- **Example 13.** If the points (0,1,-2),  $(3,\lambda,-1)$  and  $(\mu,-3,-4)$  are collinear, verify whether the point (12,9,2) is also on the same line.
- **Sol.** Let the points be A, B and C, whose coordinates are  $(0, 1, -2), (3, \lambda, -1)$  and  $(\mu, -3, -4)$  respectively.

Let 
$$D = (12, 9, 2)$$

$$\Rightarrow$$
 DR's of  $AB = (3 - 0, \lambda - 1, -1 + 2)$ 

$$=(3, \lambda - 1, 1)$$

DR's of 
$$AC = (\mu - 0, -3 - 1, -4 - (-2))$$

$$=(\mu, -4, -2)$$

Since, *A*, *B* and *C* are collinear.

$$\Rightarrow$$
  $\frac{3}{2}$ 

$$\frac{3}{1} = \frac{\lambda - 1}{-4} = \frac{1}{-4}$$

$$\rightarrow$$
  $\mu = 6\lambda =$ 

 $\therefore$  Direction ratios of AB are (3, 2, 1).

Now, direction ratios of AD are (12 - 0, 9 - 1, 2 - (2)) or (12, 8, 4)

$$\frac{3}{12} = \frac{2}{8} = \frac{1}{4}$$

$$\therefore$$
 AB || AD

Since, AB and AD lie on same straight line.

Hence, the point (12, 9, 2) is on the same line.

- Example 14. A vector **r** has length 21 and direction ratios 2, 3, 6. Find the direction cosines and components of **r**, given that **r** makes an obtuse angle with *X*-axis.
- **Sol.** Here, direction ratio's are 2, -3, 6.

:. Direction cosines can be written as  $(2\lambda, -3\lambda, 6\lambda)$ .

where, 
$$(2\lambda)^2 + (-3\lambda)^2 + (6\lambda)^2 = 1$$
 (::  $l^2 + m^2 + n^2 = 1$ )

s 
$$49\lambda^2 = 1$$

$$\lambda = \mp \frac{1}{-}$$

$$\therefore$$
 Direction cosines are  $\left(\pm \frac{2}{7}, \mp \frac{3}{7}, \pm \frac{6}{7}\right)$ .

But it makes obtuse angle with *X*-axis  $\Rightarrow l < 0$ .

$$\therefore$$
 Direction cosines are  $\left(-\frac{2}{7}, \frac{3}{7}, -\frac{6}{7}\right)$ 

Also, 
$$\mathbf{r} = |\mathbf{r}| (l\,\hat{\mathbf{i}} + m\,\hat{\mathbf{j}} + n\,\hat{\mathbf{k}})$$

$$\Rightarrow \mathbf{r} = 21\left(-\frac{2}{7}\hat{\mathbf{i}} + \frac{3}{7}\hat{\mathbf{j}} - \frac{6}{7}\hat{\mathbf{k}}\right)$$
 (given,  $|\mathbf{r}| = 21$ )  
$$\mathbf{r} = 3\left(-2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} - 6\hat{\mathbf{k}}\right)$$

So, the component of  $\mathbf{r}$  along X, Y and Z-axes are  $-6\hat{\mathbf{i}}$ ,  $9\hat{\mathbf{j}}$  and  $-18\hat{\mathbf{k}}$ , respectively.

**Example 15.** Find the angle between the lines whose

direction cosines are 
$$\left(-\frac{\sqrt{3}}{4}, \frac{1}{4}, -\frac{\sqrt{3}}{2}\right)$$
 and

$$\left(-\frac{\sqrt{3}}{4},\frac{1}{4},\frac{\sqrt{3}}{2}\right).$$

**Sol.** Let  $\theta$  be the required angle, then

$$\cos \theta = l_1 l_2 + m_1 m_2 + n_1 n_2$$

$$=\frac{3}{16}+\frac{1}{16}-\frac{3}{4}=-\frac{1}{2}$$

$$\therefore \qquad \cos \theta = -\frac{1}{2} \implies \theta = 120^{\circ}$$

#### Example 16.

- (i) Find the angle between the lines whose direction ratios are 1, 2, 3 and -3, 2, 1.
- (ii) Find the acute angle between two diagonal of a cube.
- **Sol.** (i) Let  $\theta$  be the required angle, then

$$\cos \theta = \frac{1 \times -3 + 2 \times 2 + 3 \times 1}{\sqrt{1 + 4 + 9}} = \frac{4}{14} = \frac{2}{7}$$

$$\theta = \cos^{-1}\left(\frac{2}{7}\right)$$

(ii) From the figure given below, the direction ratios of the diagonals *OP* and *CD* of a given cube are given by

$$a - 0, a - 0, a - 0$$

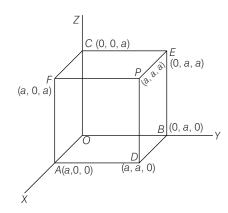

and

$$a - 0, a - 0, 0 - a$$

and hence their respective direction cosines are

$$\frac{a}{\sqrt{a^2 + a^2 + a^2}}, \frac{a}{\sqrt{a^2 + a^2 + a^2}}, \frac{-a}{\sqrt{a^2 + a^2 + a^2}}$$

i.e. 
$$\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{-1}{\sqrt{3}}$$

and 
$$\frac{a}{\sqrt{a^2 + a^2 + a^2}}$$
,  $\frac{a}{\sqrt{a^2 + a^2 + a^2}}$ ,  $\frac{-a}{\sqrt{a^2 + a^2 + a^2}}$   
i.e.  $\frac{1}{\sqrt{3}}$ ,  $\frac{1}{\sqrt{3}}$ ,  $\frac{-1}{\sqrt{3}}$ 

Let  $\theta$  be the angle between these diagonals, then

$$\cos \theta = \frac{1}{\sqrt{3}} \times \frac{1}{\sqrt{3}} + \frac{1}{\sqrt{3}} \times \frac{1}{\sqrt{3}} + \frac{1}{\sqrt{3}} \times \frac{-1}{\sqrt{3}} = \frac{1}{3} + \frac{1}{3} - \frac{1}{3} = \frac{1}{3}$$

$$\Rightarrow \theta = \cos^{-1} \left(\frac{1}{3}\right)$$

**Example 17.** Find the angle between the lines whose direction cosines are given by l + m + n = 0 and  $2l^2 + 2m^2 - n^2 = 0$ .

**Sol.** 
$$l^2 + m^2 + n^2 = 1$$

$$l + m + n = 0$$
 ...(i)  
 $2l^2 + 2m^2 - n^2 = 0$  ...(ii)

$$2(l^2 + m^2) - n^2 = 0$$

$$2(1 - n^2) = n^2 \implies 3n^2 = 2 \implies n = \pm \sqrt{\frac{2}{3}}$$
 ...(iii)

$$2(l^2 + m^2) = n^2 = (-(l+m))^2$$
 ...(iv)

$$\Rightarrow 2l^2 + 2m^2 = l^2 + m^2 + 2lm$$

$$\Rightarrow l^2 + m^2 - 2lm = 0$$

$$\Rightarrow$$
  $(l-m)^2 = 0 \Rightarrow l = m$ 

$$\Rightarrow$$
  $l+m=\mp\sqrt{\frac{2}{3}}$ 

$$\Rightarrow$$
  $2l = \mp \sqrt{\frac{2}{3}}$ 

$$\therefore \qquad l = \pm \frac{1}{\sqrt{6}}, m = \pm \frac{1}{\sqrt{6}}$$

Direction cosines are  $\left(\frac{1}{\sqrt{6}}, \frac{1}{\sqrt{6}}, \sqrt{\frac{2}{3}}\right)$  and  $\left(\frac{1}{\sqrt{6}}, \frac{1}{\sqrt{6}}, -\sqrt{\frac{2}{3}}\right)$ 

or 
$$\left(-\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, \sqrt{\frac{2}{3}}\right)$$
 and  $\left(-\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, -\sqrt{\frac{2}{3}}\right)$ 

The angle between these lines in both the cases is  $\cos^{-1}\left(-\frac{1}{3}\right)$ .

**Example 18.** If the direction cosines of a variable line in two adjacent points be l, m, n and  $l + \delta l$ ,  $m + \delta m$ ,  $n + \delta n$ , show that the small angle  $\delta \theta$  between the two positions, is given by  $\delta \theta^2 = \delta l^2 + \delta m^2 + \delta n^2$ .

**Sol.** We have,  $l^2 + m^2 + n^2 = 1$ 

and 
$$(l + \delta l)^{2} + (m + \delta m)^{2} + (n + \delta n)^{2} = 1$$

$$\Rightarrow l^{2} + m^{2} + n^{2} + (\delta l)^{2} + (\delta m)^{2} + (\delta n)^{2} + 2(l\delta l + m\delta m + n\delta n) = 1$$

$$\Rightarrow 1 + (\delta l)^{2} + (\delta m)^{2} + (\delta n)^{2} + 2(l\delta l + m\delta m + n\delta n) = 1$$

$$\Rightarrow (\delta l)^{2} + (\delta m)^{2} + (\delta n)^{2} = -2(l\delta l + m\delta m + n\delta n) \qquad ...(i)$$

Let  $\delta\theta$  be angle between the two positions.

$$\cos \delta \theta = l(l + \delta l) + m(m + \delta m) + n(n + \delta n)$$
 
$$\Rightarrow 1 - 2\sin^2 \frac{\delta \theta}{2} = 1 + l\delta l + m\delta m + n\delta n \qquad ...(ii)$$

From Eqs. (i) and (ii), we get

$$(\delta l)^{2} + (\delta m)^{2} + (\delta n)^{2} = 4 \sin^{2} \frac{\delta \theta}{2}$$

$$\Rightarrow 4\left(\frac{\delta\theta}{2}\right)^2 = l\delta l + m\delta m + n\delta n$$

$$\Rightarrow \qquad l\delta l + m\delta m + n\delta n = (\delta \theta)^2,$$

$$\left(\text{since, } \sin\frac{\delta\theta}{2} \to \frac{\delta\theta}{2} \text{ as } \delta\theta \text{ is very small}\right)$$

**Example 19.** If  $l_1$ ,  $m_1$ ,  $n_1$  and  $l_2$ ,  $m_2$ ,  $n_2$  are the direction cosines of two mutually perpendicular lines, shows that the direction cosines of the line perpendicular to both of them are  $m_1n_2 - m_2n_1$ ;  $n_1l_2 - n_2l_1$ ;  $l_1m_2 - l_2m_1$ .

**Sol.** Let *l*, *m* and *n* be the direction cosines of the line perpendicular to both the given lines.

$$\begin{array}{ll} \therefore & ll_1 + mm_1 + nn_1 = 0 \quad \text{and} \quad ll_2 + mm_2 + nn_2 = 0 \\ \\ \text{Solving them, we get} \quad \frac{l}{m_1 - n_1} = \frac{m}{n_1 - l_1} = \frac{n}{l_1 - m_1} \\ \\ m_2 - n_2 - n_2 - l_2 - l_2 - m_2 \end{array}$$

$$\Rightarrow \frac{l}{m_1 n_2 - m_2 n_1} = \frac{m}{n_1 l_2 - n_2 l_1} = \frac{n}{l_1 m_2 - l_2 m_1} = k$$

$$\label{eq:local_local_local} \therefore \quad l = k(m_1n_2 - m_2n_1) \;, \; m = k(n_1l_2 - n_2l_1), \; n = k(l_1m_2 - l_2m_1)$$

On squaring and adding, we get

$$l^{2} + m^{2} + n^{2} = k^{2} \{ (m_{1}n_{2} - m_{2}n_{1})^{2} + (n_{1}l_{2} - n_{2}l_{1})^{2} \} + (l_{1}m_{2} - l_{2}m_{1})^{2}$$

$$\Rightarrow 1 = k^{2} \{ \sin^{2} \theta \}$$

where,  $\theta$  is the angle between the given lines as we know,

$$\sin \theta = \sqrt{(a_1b_2 - a_2b_1)^2 + (b_1c_2 - b_2c_1)^2 + (c_1a_2 - c_2a_1)^2}$$

where,  $a_1$ ,  $b_1$ ,  $c_1$  and  $a_2$ ,  $b_2$ ,  $c_2$  are direction cosines.

$$\Rightarrow 1 = k^2 \cdot 1 \qquad (\because \theta = 90^\circ, \text{ given})$$

$$\Rightarrow k = 1$$

Hence, direction cosines of a line perpendicular to both of them are  $m_1n_2 - m_2n_1$ ,  $n_1l_2 - n_1l_2$ ,  $l_1m_2 - l_2m_1$ .

- **Example 20.** Find the direction cosines of the line which is perpendicular to the lines with direction cosines proportional to (1, -2, -2) and (0, 2, 1).
- **Sol.** If l, m and n are the direction cosines of the line perpendicular to the given line, then

$$l \cdot (1) + m \cdot (-2) + n \cdot (-2) = 0$$
  $\Rightarrow$  
$$l - 2m - 2n = 0$$
 ...(i) and 
$$l \cdot 0 + m \cdot 2 + n \cdot 1 = 0$$
 
$$0 + 2m + n = 0$$
 ...(ii)

Then, from Eqs. (i) and (ii) by cross multiplication, we get

$$\frac{l}{2} = \frac{m}{-1} = \frac{n}{2}$$

$$\frac{l}{2} = \frac{m}{-1} = \frac{n}{2}$$

$$= \frac{\sqrt{l^2 + m^2 + n^2}}{\sqrt{4 + 1 + 4}} = \frac{1}{3} \qquad (\because l^2 + m^2 + n^2 = 1)$$

$$\Rightarrow \qquad l = \frac{2}{3}, m = -\frac{1}{3},$$

$$n = \frac{2}{3}$$

- **Example 21.** Let A (-1, 2, 1) and B (4, 3, 5) be two given points. Find the projection of AB on a line which makes angle  $120^{\circ}$  and  $135^{\circ}$  with Y and Z-axes respectively, and an acute angle with X-axis.
- **Sol.** Let  $\alpha$  be an acute angle that the given line make with X-axis. Then,  $\cos^2 \alpha + \cos^2 120^\circ + \cos^2 135^\circ = 1$

$$\Rightarrow$$
  $\cos^2 \alpha = 1 - \frac{1}{4} - \frac{1}{2} = \frac{4 - 2 - 1}{4} = \frac{1}{4}$ 

$$\Rightarrow$$
  $\cos \alpha = \pm \frac{1}{2} \operatorname{but} \alpha \text{ is acute}$ 

$$\therefore$$
  $\cos \alpha = + ve$ 

$$\Rightarrow \qquad \cos \alpha = \frac{1}{2} = \cos 60^{\circ} \Rightarrow \alpha = 60^{\circ}$$

Thus, the direction cosines of the given straight line are  $\cos 60^{\circ}$ ,  $\cos 120^{\circ}$ ,  $\cos 135^{\circ}$ , i.e.  $\frac{1}{2}$ ,  $-\frac{1}{2}$ ,  $-\frac{1}{\sqrt{2}}$ 

Hence the projection of *AB* on the line

$$= \frac{1}{2}(4+1) - \frac{1}{2}(3-2) - \frac{1}{\sqrt{2}}(5-1) = \frac{5}{2} - \frac{1}{2} - 2\sqrt{2}$$
$$= (2 - 2\sqrt{2}) \text{ units}$$

# **Session 2**

# Equation of a Straight Line in Space, Angle between Two Lines, Perpendicular Distance of a Point from a Line, Shortest Distance between Two Lines

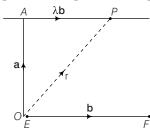

# **Equation of a Straight Line** in Space

A straight line in space is specified basically in two ways

- (i) A line passing through a given point and parallel to a given vector.
- (ii) A line passing through any two given points.

# 1. Vector Equation of a Line Passing Through a Given Point and Parallel to a Given Vector

To find the vector equation of a straight line which passes through a given point and is parallel to a given vector.

Let A be the given point and let EF be the given line, then through A draw AP parallel to given line EF.

Let **b** any vector parallel to the given line. Take any point *O* as the origin of reference. Let a the position vector of the given point *A*.

Let P be any point on the AP and let its position vector be  $\mathbf{r}$ . Then, we have

$$r = OP = OA + AP = a + \lambda b$$
 (where,  $AP = \lambda b$ )

Hence, the vector equation of straight line

$$\mathbf{r} = \mathbf{a} + \lambda \mathbf{b} \qquad \dots (i)$$

#### Remarks

- **1.** Here, **r** is the position vector of any point P(x, y, z) on the line  $\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$ .
- **2.** In particular, the equation of the straight line through origin and parallel to  $\bf b$  is  $\bf r=\lambda \bf b$ .

#### 2. Cartesian Equation of a Line Passing Through a Given Point and Given Direction Ratios

Let the coordinates of the given point A be  $(x_1, y_1, z_1)$  and the direction ratios of the line be a, b and c. Consider the coordinate of any point P be (x, y, z). Then,

$$\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}};$$
  

$$\mathbf{a} = x_1\hat{\mathbf{i}} + y_1\hat{\mathbf{j}} + z_1\hat{\mathbf{k}}$$
  

$$\mathbf{b} = a\hat{\mathbf{i}} + b\hat{\mathbf{j}} + c\hat{\mathbf{k}}$$

and

Substituting these values in (i) and equating the coefficients of  $\hat{\mathbf{i}}$ ,  $\hat{\mathbf{j}}$  and  $\hat{\mathbf{k}}$ , we get

$$x = x_1 + \lambda a$$
$$y = y_1 + \lambda b$$
$$z = z_1 + \lambda c$$

These are parametric equations of the line.

Eliminating the parameter  $\lambda$ , we get

$$\frac{x-x_1}{a} = \frac{y-y_1}{b} = \frac{z-z_1}{c}.$$

#### Remarks

1. Parametric equation of straight line

$$\frac{x - x_1}{a} = \frac{y - y_1}{b} = \frac{z - z_1}{c} = \lambda$$

$$\Rightarrow \qquad x = x_1 + \lambda a, \ y = y_1 + \lambda b, \ z = z_1 + \lambda c$$
(where,  $\lambda$  being parameter)

- **2.** Since, *X*, *Y* and *Z*-axes pass through origin and have direction cosines (1, 0, 0), (0, 1, 0) and (0, 0, 1).
  - ::Their equations are

Equation of X-axis, 
$$\frac{x-0}{1} = \frac{y-0}{0} = \frac{z-0}{0}$$

$$\Rightarrow \qquad y = 0 \text{ and } z = 0$$
Equation of Y-axis,  $\frac{x-0}{0} = \frac{y-0}{1} = \frac{z-0}{0}$ 

$$\Rightarrow \qquad x = 0 \text{ and } z = 0$$
Equation of Z-axis,  $\frac{x-0}{0} = \frac{y-0}{0} = \frac{z-0}{1}$ 

- **Example 22.** Find the equation of straight line parallel to  $2\hat{i} - \hat{j} + 3\hat{k}$  and passing through the point (5, -2, 4).
- **Sol.** Vector form Let P = (5, -2, 4), then  $\mathbf{OP} = 5\hat{\mathbf{i}} 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}} = \mathbf{a}$

Also, 
$$\mathbf{b} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}$$

So, equation of straight line passing through a and parallel to straight line whose direction ratios are  $\mathbf{b}$  is given as

$$\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$$

$$\Rightarrow \qquad \mathbf{r} = (5\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) + \lambda(2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}})$$

**Cartesian form** Here,  $(x_1, y_1, z_1) = (5, -2, 4)$  and parallel to straight line whose DR's are (2, -1, 3), so equation of the straight line is  $\frac{x-5}{2} = \frac{y+2}{-1} = \frac{z-4}{3}$ .

- **Example 23.** Find the vector equation of a line passing through (2, -1, 1) and parallel to the line whose equation is  $\frac{x-3}{2} = \frac{y+1}{7} = \frac{z-2}{-3}$
- **Sol.** Since, the required line is parallel to

$$\frac{x-3}{2} = \frac{y+1}{7} = \frac{z-2}{-3}$$

it follows that the required line passing through  $A(2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}})$  has the direction of  $2\hat{\mathbf{i}} + 7\hat{\mathbf{j}} - 3\hat{\mathbf{k}}$ . Hence, the vector equation of the required line is  $\mathbf{r} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}} + \lambda(2\hat{\mathbf{i}} + 7\hat{\mathbf{j}} - 3\hat{\mathbf{k}})$  where  $\lambda$  is a parameter.

- **Example 24.** The cartesian equation of a line are 6x - 2 = 3y + 1 = 2z - 2. Find its direction ratios and also find the vector equation of the line.
- Sol. We know that,

$$\frac{x-x_1}{a} = \frac{y-y_1}{b} = \frac{z-z_1}{c}$$
 is cartesian equation of straight line.  
∴ 
$$6x-2 = 3y+1 = 2z-2$$

$$\therefore 6x - 2 = 3y + 1 = 2z - 2$$

$$\Rightarrow 6\left(x - \frac{1}{3}\right) = 3\left(y + \frac{1}{3}\right) = 2(z - 1)$$

$$\Rightarrow \frac{x - \frac{1}{3}}{\frac{1}{6}} = \frac{y + \frac{1}{3}}{\frac{1}{3}} = \frac{z - 1}{\frac{1}{2}}$$

$$\Rightarrow \frac{x - \frac{1}{3}}{1} = \frac{y + \frac{1}{3}}{2} = \frac{z - 1}{3}$$

which shows given line passes through  $\left(\frac{1}{3}, -\frac{1}{3}, 1\right)$  and has direction ratios (1, 2, 3).

:. Its vector equation is

$$\mathbf{r} = \left(\frac{1}{3}\hat{\mathbf{i}} - \frac{1}{3}\hat{\mathbf{j}} + \hat{\mathbf{k}}\right) + \lambda(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})$$

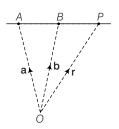

#### 3. Vector Equation of a Line Passing Through Two Given Points

The vector equation of a line passing through two points whose position vectors **a** and **b** is

$$\mathbf{r} = a + \lambda(\mathbf{b} - \mathbf{a})$$

Let *O* be the origin and *A* and *B* be the given points with position vectors **a** and **b**, respectively.

Then. 
$$OP = r$$
,  $OA = a$  and  $OB = b$ 

Since, AP is collinear with AB.

$$\therefore$$
 **AP** =  $\lambda$  **AB** for some scalar  $\lambda$ 

$$\Rightarrow \qquad \mathbf{OP} - \mathbf{OA} = \lambda(\mathbf{OB} - \mathbf{OA})$$

$$\Rightarrow \qquad \qquad \mathbf{r} - \mathbf{a} = \lambda(\mathbf{b} - \mathbf{a})$$

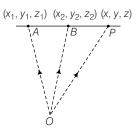

$$\mathbf{r} = \mathbf{a} + \lambda(\mathbf{b} - \mathbf{a})$$

∴ Equation of straight line passing through **a** and **b**.

$$\Rightarrow$$
  $\mathbf{r} = \mathbf{a} + \lambda(\mathbf{b} - \mathbf{a})$ 

#### 4. Cartesian Equation of a Line Passing Through Two Given Points

Equation of straight line passing through  $(x_1, y_1, z_1)$ ,  $(x_2, y_2, z_2).$ 

The direction ratios of

$$AB = (x_2 - x_1, y_2 - y_1, z_2 - z_1)$$

The direction ratios of

$$AP = (x - x_1, y - y_1, z - z_1)$$

Since, they are proportional

$$\frac{x - x_1}{x_2 - x_1} = \frac{y - y_1}{y_2 - y_1}$$
$$= \frac{z - z_1}{z_2 - z_1}$$

**Example 25.** Find the vector equation of line passing through A(3,4,-7) and B(1,-1,6). Also, find its cartesian equations.

**Sol.** Since, the line passes through  $A(3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 7\hat{\mathbf{k}})$ and  $B(\hat{\mathbf{i}} - \hat{\mathbf{j}} + 6\hat{\mathbf{k}})$ , its vector equation is

$$\mathbf{r} = 3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 7\hat{\mathbf{k}} + \lambda[(\hat{\mathbf{i}} - \hat{\mathbf{j}} + 6\hat{\mathbf{k}}) - (3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 7\hat{\mathbf{k}})]$$
or 
$$\mathbf{r} = 3\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 7\hat{\mathbf{k}} - \lambda(2\hat{\mathbf{i}} + 5\hat{\mathbf{j}} - 13\hat{\mathbf{k}})$$
 ...(

where  $\lambda$  is a parameter.

The cartesian equivalent of (i) is  $\frac{x-3}{2} = \frac{y-4}{5} = \frac{z+7}{-13}$ 

**Example 26.** Find the equation of a line which passes through the point (2, 3, 4) and which has equal intercepts on the axes.

**Sol.** Since, lines has equal intercepts on axes, it is equally inclined to axes.

- $\Rightarrow$  line is along the vector  $a(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}})$
- $\Rightarrow$  Equation of line is  $\frac{x-2}{1} = \frac{y-3}{1} = \frac{z-4}{1}$

# Angle between Two Lines

#### **Vector Form**

Let  $r = a + \lambda b$ ...(i)

and 
$$\mathbf{r} = \mathbf{a'} + \mu \mathbf{b'}$$
 ...(ii)

be two straight line in space.

Clearly, Eqs. (i) and (ii) are straight line in the directions of **b** and **b'**, respectively.

Let  $\theta$  be the between the straight lines (i) and (ii).

Then,  $\theta$  is the angle between the vectors **b** and **b**' also

$$\mathbf{b} \cdot \mathbf{b'} = |\mathbf{b}| |\mathbf{b'}| \cos \theta$$

$$\Rightarrow$$

$$\cos \theta = \frac{\mathbf{b} \cdot \mathbf{b'}}{|\mathbf{b}| |\mathbf{b'}|}$$

#### Cartesian Form

$$\frac{x - x_1}{a_1} = \frac{y - y_1}{b_1} = \frac{z - z_1}{c_1} \qquad \dots (i)$$

and

$$\frac{x - x_2}{a_2} = \frac{y - y_2}{b_1} = \frac{z - z_2}{c_2} \qquad ...(ii)$$

be two straight lines. Then,  $\mathbf{b} = a_1 \hat{\mathbf{i}} + b_1 \hat{\mathbf{j}} + c_1 \hat{\mathbf{k}}$ 

$$\mathbf{b'} = a_2 \,\hat{\mathbf{i}} + b_2 \,\hat{\mathbf{j}} + c_2 \,\hat{\mathbf{k}}$$

So, that

$$\mathbf{b} \cdot \mathbf{b'} = a_1 a_2 + b_1 b_2 + c_1 c_2$$

and

$$|\mathbf{b}| = \sqrt{a_1^2 + b_1^2 + c_1^2}$$
;  $|\mathbf{b'}| = \sqrt{a_2^2 + b_2^2 + c_2^2}$ 

$$\therefore \qquad \cos \theta = \frac{a_1 a_2 + b_1 b_2 + c_1 c_2}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}}$$

## **Condition for Perpendicularity**

The lines are perpendicular, then

$$\mathbf{b} \cdot \mathbf{b'} = 0$$

$$\Rightarrow$$

$$a_1 a_2 + b_1 b_2 + c_1 c_2 = 0$$

## **Condition for Parallelism**

The lines are parallel, then  $\mathbf{b} = (\mathbf{b'}) \lambda$ , for some scalar  $\lambda$ 

$$\Rightarrow$$

$$\frac{a_1}{a_2} = \frac{b_1}{b_2} = \frac{c_1}{c_2}$$

**Example 27.** Find the angle between the pair of lines

$$\mathbf{r} = 3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 4\hat{\mathbf{k}} + \lambda (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

and

$$\mathbf{r} = 5\,\hat{\mathbf{i}} - 2\hat{\mathbf{k}} + \mu(3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 6\,\hat{\mathbf{k}})$$

**Sol.** Given line are

$$\mathbf{r} = (3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 4\hat{\mathbf{k}}) + \lambda(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

$$\mathbf{r} = (5\hat{\mathbf{i}} - 2\hat{\mathbf{k}}) + \mu(3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 6\hat{\mathbf{k}})$$

We know that, angle between  $\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_1$  and  $\mathbf{r} = \mathbf{a}_2 + \mu \mathbf{b}_2$ ,

$$\cos \theta = \frac{\mathbf{b}_1 \cdot \mathbf{b}_2}{|\mathbf{b}_1| |\mathbf{b}_2|}$$

$$\therefore \cos \theta = \frac{(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) \cdot (3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 6\hat{\mathbf{k}})}{\sqrt{1^2 + 2^2 + 2^2}} \frac{3 + 4 + 12}{\sqrt{3^2 + 2^2 + 6^2}} = \frac{3 + 4 + 12}{\sqrt{9} \cdot \sqrt{49}} = \frac{19}{21}$$

$$\therefore \qquad \theta = \cos^{-1}\left(\frac{19}{21}\right)$$

**Example 28.** Prove that the line x = ay + b, z = cy + dand x = a'y + b', z = dy + d' are perpendicular, if aa' + cc' + 1 = 0.

**Sol.** We can write the equations of straight line as

$$\frac{x-b'}{a'} = y, y = \frac{z-d'}{c'}$$

$$\Rightarrow \frac{a}{\frac{x-b'}{a'}} = \frac{y-0}{1} = \frac{z-d'}{c'} \qquad \dots (i)$$

$$\frac{x-b}{a} = y, \ y = \frac{z-d}{c}$$

$$\Rightarrow \frac{x-b}{a} = \frac{y-0}{1} = \frac{z-d_2}{c} \qquad \dots (ii)$$

We know that,  $\frac{x - x_1}{a_1} = \frac{y - y_1}{b_1} = \frac{z - z_1}{c_1}$ 

$$\frac{x - x_2}{a} = \frac{y - y_2}{b} = \frac{z - z_2}{a}$$

are perpendicular, if  $a_1a_2 + b_1b_2 + c_1c_2 = 0$ 

.. For the straight lines given by Eqs. (i) and (ii), to be perpendicular.

$$a'a + 1 \cdot 1 + c'c = 0$$

$$aa'+cc'+1=0$$

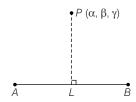

# Perpendicular Distance of a Point from a Line

# 1. Foot of Perpendicular from a Point on the Given Line

(i) **Cartesian Form** Here, the equation of line *AB* is  $\frac{x - x_1}{a} = \frac{y - y_1}{b} = \frac{z - z_1}{c}$ 

Let *L* be the foot of the perpendicular drawn from  $P(\alpha, \beta, \gamma)$  on the line  $\frac{x - x_1}{a} = \frac{y - y_1}{b} = \frac{z - z_1}{c}$ .

Let the coordinates of *L* be  $(x_1 + a\lambda, y_1 + b\lambda, z_1 + c\lambda)$ . Then, the direction ratios of *PL* are  $(x_1 + a\lambda - \alpha, y_1 + b\lambda - \beta, z_1 + c\lambda - \gamma)$ .

Direction ratios of AB are (a, b, c).

Since PL is perpendicular to AB.

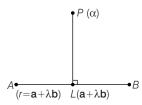

$$a(x_1 + a\lambda - \alpha) + b(y_1 + b\lambda - \beta) + c(z_1 + c\lambda - \gamma) = 0$$
$$\lambda = \frac{a(\alpha - x_1) + b(\beta - y_1) + c(\gamma + z_1)}{a^2 + b^2 + c^2}$$

Putting the value of  $\lambda$  in  $(x_1 + a\lambda, y_1 + b\lambda, z_1 + c\lambda)$ , we get the foot of the perpendicular. Now, we can get distance *PL* using distance formula.

(ii) **Vector Form** Let *L* be the foot of the perpendicular drawn from  $P(\alpha)$  on the line  $\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$ .

Since, **r** denotes the position vector of any point on the line  $\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$ , the position vector of L will be  $(\mathbf{a} + \lambda \mathbf{b})$ 

Directions ratios of  $PL = \mathbf{a} - \alpha + \lambda \mathbf{b}$ 

Since, **PL** is perpendicular to **b**,

$$(\mathbf{a} - \alpha + \lambda \mathbf{b}) \cdot \mathbf{b} = 0$$

$$\Rightarrow (\mathbf{a} - \alpha) \cdot \mathbf{b} + \lambda \mathbf{b} \cdot \mathbf{b} = 0$$

$$\Rightarrow \qquad \lambda = \frac{-(\mathbf{a} - \alpha) \cdot \mathbf{b}}{|\mathbf{b}|^2}$$

 $\Rightarrow$  Position vector of L is  $\mathbf{a} - \left(\frac{(\mathbf{a} - \alpha) \cdot \mathbf{b}}{|\mathbf{b}|^2}\right) \mathbf{b}$ , which is

the foot of the perpendicular.

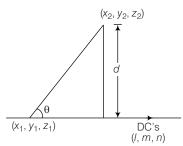

(iii) The distance of the point  $(x_2, y_2, z_2)$  from the line  $\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}$ , (where l, m and n are

direction cosines of the line), is

$$[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2 - \{l(x_2 - x_1) + m(y_2 - y_1) + n(z_2 - z_1)\}^2]^{1/2}$$
Let 
$$\mathbf{r}_1 = (x_2 - x_1)\hat{\mathbf{i}} + (y_2 - y_1)\hat{\mathbf{j}} + (z_2 - z_1)\hat{\mathbf{k}}$$

$$\mathbf{r}_2 = l\hat{\mathbf{i}} + m\hat{\mathbf{j}} + n\hat{\mathbf{k}}$$

$$\therefore \qquad \cos \theta = \frac{\mathbf{r}_2 \cdot \mathbf{r}_1}{|\mathbf{r}_2| \cdot |\mathbf{r}_1|}$$

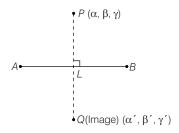

Also, 
$$d = |\mathbf{r}_{1}| \sin \theta$$
  
 $d^{2} = |\mathbf{r}_{1}|^{2} \sin^{2} \theta$   
 $= |\mathbf{r}_{1}|^{2} (1 - \cos^{2} \theta)$   
 $= |\mathbf{r}_{1}|^{2} \left(1 - \frac{(\mathbf{r}_{1} \cdot \mathbf{r}_{2})^{2}}{|\mathbf{r}_{1}|^{2} \cdot |\mathbf{r}_{2}|^{2}}\right)$   
 $d^{2} = |\mathbf{r}_{1}|^{2} - (\mathbf{r}_{1} \cdot \mathbf{r}_{2})^{2}$  (where,  $|\mathbf{r}_{2}| = 1$ )  
 $\Rightarrow d = \sqrt{|\mathbf{r}_{1}|^{2} - (\mathbf{r}_{1} \cdot \mathbf{r}_{2})^{2}}$   
 $d = \sqrt{\{(x_{2} - x_{1})^{2} + (y_{2} - y_{1})^{2} + (z_{2} - z_{1})^{2} - \{l(x_{2} - x_{1}) + m(y_{2} - y_{1}) + n(z_{2} - z_{1})\}^{2}}$ 

# 2. Reflection or Image of a Point in a Straight Line

(i) **Cartesian Form** To find the reflection or image of a point in a straight line in cartesian form.

Let  $P(\alpha, \beta, \gamma)$  be the point and

$$\frac{x - x_1}{a} = \frac{y - y_1}{b} = \frac{z - z_1}{c}$$
 be the given line.

Let *L* be the foot of perpendicular from *P* to *AB* and let Q be the image of the point in the given line, where PL = LQ.

Let the coordinates of *L* be

$$(x_1 + a\lambda, y_1 + b\lambda, z_1 + c\lambda)$$

Then, direction ratios of PL are

$$(x_1 + a\lambda - \alpha, y_1 + b\lambda - \beta, z_1 + c\lambda - \gamma)$$

Since, PL is perpendicular to the given line, whose direction ratios are *a*, *b* and *c*.

$$\therefore (x_1 + a\lambda - \alpha) \cdot a + (y_1 + b\lambda - \beta) \cdot b$$

$$+ (z_1 + c\lambda - \gamma) \cdot c = 0$$

$$\Rightarrow \qquad \lambda = \frac{\{a(\alpha - x_1) + b(\beta - y_1) + c(\gamma - z_1)\}}{a^2 + b^2 + c^2}$$

Substituting  $\lambda$ , we get L, (foot of perpendicular) Let coordinates of  $Q(\alpha', \beta', \gamma')$  be image.

 $\therefore$  Mid-point of *PQ* is *L*.

$$\therefore \frac{\alpha + \alpha'}{2} = x_1 + a\lambda, \frac{\beta + \beta'}{2} = y_1 + b\lambda, \frac{\gamma + \gamma'}{2} = z_1 + c\lambda$$

$$\therefore \alpha' = 2(x_1 + a\lambda) - \alpha, \beta' = 2(y_1 + b\lambda) - \beta,$$

$$\gamma' = 2(z_1 + c\lambda) - \gamma$$

(ii) Vector Form To find the reflection or image of a point in a straight line in vector form. Let  $P(\alpha)$  be the given point and  $\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$  be the given line.

Let *Q* be the image of *P* in  $\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$ 

$$\therefore$$
 PL =  $\mathbf{a} + \lambda \mathbf{b} - \alpha$ 

Since, **PL** is perpendicular to the given line,

$$\therefore \qquad PL \perp \mathbf{b}$$

$$\Rightarrow \qquad PL \cdot \mathbf{b} = 0$$

$$\Rightarrow \qquad (\mathbf{a} + \lambda \mathbf{b} - \alpha) \cdot \mathbf{b} = 0$$

$$\Rightarrow \qquad \lambda = -\frac{[(\mathbf{a} - \alpha) \cdot \mathbf{b}]}{|\mathbf{b}|^2}$$

 $\therefore$  Position vector of L,

$$\mathbf{a} + \lambda \mathbf{b} = \mathbf{a} - \left(\frac{(\mathbf{a} - \alpha) \cdot \mathbf{b}}{|\mathbf{b}|^2}\right) \mathbf{b}$$

Let Q be the image of point P and  $\alpha'$  be the position vector.

Since, *L* is mid-point of *PQ*.

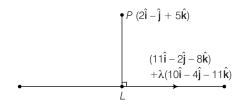

$$\Rightarrow \frac{\alpha + \alpha'}{2} = \mathbf{a} - \left(\frac{(\mathbf{a} - \alpha) \cdot \mathbf{b}}{|\mathbf{b}|^2}\right) \mathbf{b}$$

$$\Rightarrow \qquad \alpha' = 2\mathbf{a} - \left(\frac{2(\mathbf{a} - \alpha) \cdot \mathbf{b}}{|\mathbf{b}|^2}\right)\mathbf{b} - \alpha$$

which is image of P on  $\mathbf{r}$ .

**Example 29.** Find the foot of perpendicular drawn from the point  $2\mathbf{i} - \mathbf{j} + 5\mathbf{k}$  to the line  $\mathbf{r} = (11\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 8\hat{\mathbf{k}}) + \lambda (10\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 11\hat{\mathbf{k}})$ . Also, find the length of the perpendicular.

**Sol.** Let *L* be the foot of the perpendicular drawn from  $P(2\mathbf{i} - \mathbf{j} + 5\mathbf{k})$  on the line

$$\mathbf{r} = (11\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 8\hat{\mathbf{k}}) + \lambda(10\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 11\hat{\mathbf{k}})$$

Let the position vector of L is

$$(11\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 8\hat{\mathbf{k}}) + \lambda(10\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 11\hat{\mathbf{k}})$$
$$= (11 + 10\lambda)\hat{\mathbf{i}} + (-2 - 4\lambda)\hat{\mathbf{j}} + (-8 - 11\lambda)\hat{\mathbf{k}}$$

∴**PL** = Position vector of L – Position vector of P $= (9 + 10\lambda)\hat{\mathbf{i}} + (-1 - 4\lambda)\hat{\mathbf{j}} + (-13 - 11\lambda)\hat{\mathbf{k}}$ 

$$= (9 + 10\lambda)\mathbf{I} + (-1 - 4\lambda)\mathbf{J} + (-13 - 11\lambda)\mathbf{K}$$

Since, PL is perpendicular to the given line and parallel to

$$\mathbf{b} = 10\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 11\hat{\mathbf{k}}. \implies \mathbf{PL} \cdot \mathbf{b} = 0$$

$$\implies \{(9 + 10\lambda)\hat{\mathbf{i}} + (-1 - 4\lambda)\hat{\mathbf{j}} + (-13 - 11\lambda)\hat{\mathbf{k}}\} \cdot (10\hat{\mathbf{i}} - 4\hat{\mathbf{j}} - 11\hat{\mathbf{k}}) = 0$$

$$\implies 10(9 + 10\lambda) - 4(-1 - 4\lambda) - 11(-13 - 11\lambda) = 0$$

$$\implies \lambda = -1$$

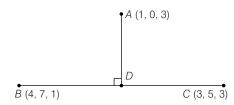

On putting  $\lambda = -1$ , we get L as  $(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})$ 

Now, 
$$\mathbf{PL} = (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}) - (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 5\hat{\mathbf{k}})$$
  
=  $(-\hat{\mathbf{i}} + 3\hat{\mathbf{i}} - 2\hat{\mathbf{k}})$ 

Hence, the length of perpendicular from *P* on the given line  $= | PL | = \sqrt{1 + 9 + 4} = \sqrt{14}$

 and  $\frac{3\lambda+1}{\lambda+1}$ .

Now, 
$$AD \perp BC \Rightarrow AD \cdot BC = 0$$

Direction ratio's of PQ are(2r-3, 3r+6, -r-3).

Direction ratio's of AB are (2, 3, -1).

Since, 
$$PQ \perp AB$$

$$2(2r-3) + 3(3r+6) - 1(-r-3) = 0$$

$$\Rightarrow \qquad r = -\frac{15}{14}$$

$$\therefore Q = \left(-\frac{22}{7}, -\frac{3}{14}, -\frac{13}{14}\right)$$

$$PQ^2 = \left(2 + \frac{22}{7}\right)^2 + \left(-3 + \frac{3}{14}\right)^2 + \left(1 + \frac{13}{14}\right)^2 = \frac{531}{14}$$

$$PQ = \sqrt{\frac{531}{14}}$$

$$\frac{x-4}{-2} = \frac{y}{6} = \frac{z-1}{-3} = k \text{ (say)}. \qquad \dots \text{(i)}$$

As P lies on (i), coordinates of P are (4-2k, 6k, 1-3k) for some value of k.

The direction ratios of *AP* are

$$(2-2k, 6k-3, -3-3k)$$
.

Also, the direction ratios of l are -2, 6 and -3.

Since,  $AP \perp l$ 

$$\Rightarrow -2(2-2k) + 6(6k-3) - 3(-3-3k) = 0$$

$$\Rightarrow$$
  $-4 + 4k + 36k - 18 + 9 + 9k = 0$

We have, 
$$AP^2 = (4 - 2k - 2)^2 + (6k - 3)^2 + (1 - 3k - 4)^2$$
  
 $= (2 - 2k)^2 + (6k - 3)^2 + (-3 - 3k)^2$

Direction ratios of the given line are (1, 2, 3) which is perpendicular to PL

So, coordinates of L are (1, 3, 5).

Let  $Q(x_1, y_1, z_1)$  be the image of P(1, 6, 3) on given line.

# **Shortest Distance between Two Lines**

If two lines in space intersect at a point, then the shortest distance between them is zero. Also, if two lines in space are parallel, then the shortest distance between them will be the perpendicular distance, i.e. the length of the perpendicular drawn from any point on one line onto the other line. Further, in a space, there are lines which are neither intersecting nor parallel. In fact, such pair of lines are non-coplanar and are called skew lines.

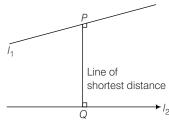

Line GE goes diagonally across the ceiling and line DB passes through one corner of the ceiling directly above A and goes diagonally down the wall. These lines are skew because they are not parallel and also never meet.

By the shortest distance between two lines, we mean the join of a point in one line with one point on the other line so that the length of the segment so obtained is the smallest.

#### Shortest Distance between Two Skew Straight Lines

#### Line of Shortest Distance

If  $l_1$  and  $l_2$  are two skew lines, then there is one and only one line perpendicular to each of lines  $l_1$  and  $l_2$  which is known as the line of shortest distance.

Here, distance *PQ* is called to be shortest distance.

#### **Vector Form**

Let  $l_1$  and  $l_2$  be two lines whose equations are  $\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_1$  and  $\mathbf{r} = \mathbf{a}_2 + \mu \mathbf{b}_2$ , respectively.

Clearly,  $l_1$  and  $l_2$  pass through the points A and B with  $\mathbf{a}_1$  and  $\mathbf{a}_2$ , respectively and are parallel to the vectors  $\mathbf{b}_1$  and  $\mathbf{b}_2$ , respectively.

Since, **PQ** is perpendicular to both  $l_1$  and  $l_2$  which are parallel to  $\mathbf{b}_1$  and  $\mathbf{b}_2$ .

 $\therefore$  **PQ** is parallel to  $\mathbf{b}_1 \times \mathbf{b}_2$ .

Let  $\hat{\mathbf{n}}$  be a unit vector along **PQ**, then  $\hat{\mathbf{n}} = \pm \frac{\mathbf{b}_1 \times \mathbf{b}_2}{|\mathbf{b}_1 \times \mathbf{b}_2|}$ 

$$\therefore PQ = \text{Projection of } \mathbf{AB} \text{ on } \mathbf{PQ}$$

$$\Rightarrow \mathbf{PQ} = \mathbf{AB} \cdot \hat{\mathbf{n}}$$

$$= \pm (\mathbf{a}_2 - \mathbf{a}_1) \cdot \frac{(\mathbf{b}_1 \times \mathbf{b}_2)}{|\mathbf{b}_1 \times \mathbf{b}_2|}$$

$$= \pm \frac{(\mathbf{b}_1 \times \mathbf{b}_2) (\mathbf{a}_2 - \mathbf{a}_1)}{|\mathbf{b}_1 \times \mathbf{b}_2|}$$
Hence, distance  $PQ = \left| \frac{(\mathbf{b}_1 \times \mathbf{b}_2) \cdot (\mathbf{a}_2 - \mathbf{a}_1)}{|\mathbf{b}_1 \times \mathbf{b}_2|} \right|$ 

$$= \frac{[\mathbf{b}_1 \mathbf{b}_2 (\mathbf{a}_2 - \mathbf{a}_1)]}{|\mathbf{b}_1 \times \mathbf{b}_2|}$$

#### Condition for Lines to Intersecting

The two lines are intersecting, if

$$\left| \frac{(\mathbf{b}_1 \times \mathbf{b}_2) \cdot (\mathbf{a}_2 - \mathbf{a}_1)}{|\mathbf{b}_1 \times \mathbf{b}_2|} \right| = 0$$

$$\Rightarrow \qquad (\mathbf{b}_1 \times \mathbf{b}_2) \cdot (\mathbf{a}_2 - \mathbf{a}_1) = 0$$

$$\Rightarrow \qquad [\mathbf{b}_1 \mathbf{b}_2 (\mathbf{a}_2 - \mathbf{a}_1)] = 0$$

#### **Cartesian Form**

Let the two skew lines be

and 
$$\frac{x - x_1}{a_1} = \frac{y - y_1}{b_1} = \frac{z - z_1}{c_1}$$
$$\frac{x - x_2}{a_2} = \frac{y - y_2}{b_2} = \frac{z - z_2}{c_2}$$

Vector equations for these two lines are

$$\mathbf{r} = (x_1 \hat{\mathbf{i}} + y_1 \hat{\mathbf{j}} + z_1 \hat{\mathbf{k}}) + \lambda (a_1 \hat{\mathbf{i}} + b_1 \hat{\mathbf{j}} + c_1 \hat{\mathbf{k}})$$
and
$$\mathbf{r} = (x_2 \hat{\mathbf{i}} + y_2 \hat{\mathbf{j}} + z_2 \hat{\mathbf{k}}) + \mu (a_2 \hat{\mathbf{i}} + b_2 \hat{\mathbf{j}} + c_2 \hat{\mathbf{k}})$$

$$\therefore \text{Shortest distance } n = \begin{vmatrix} (\mathbf{a}_2 - \mathbf{a}_1) \cdot (\mathbf{b}_1 \times \mathbf{b}_2) \\ | \mathbf{b}_1 \times \mathbf{b}_2 | \end{vmatrix}$$

$$\Rightarrow d = \begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \end{vmatrix}$$

$$\frac{|a_2 - a_2|}{|a_1 - a_2|} + (c_1 a_2 - a_1 c_2)^2$$

$$\sqrt{+(a_1 b_2 - a_2 b_1)^2} + (c_1 a_2 - a_1 c_2)^2}$$

#### **Conditions for Lines to Intersect**

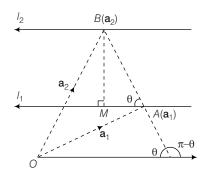

The lines are intersecting, if shortest distance = 0

$$\Rightarrow \begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \end{vmatrix} = 0$$

#### 2. Shortest Distance between Parallel Lines

Let  $l_1$  and  $l_2$  be two parallel lines whose equations are

$$\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}$$
 or  $\mathbf{r} = \mathbf{a}_2 + \mu \mathbf{b}$ , respectively.

Clearly,  $l_1$  and  $l_2$  pass through the points A and B with position vectors  $\mathbf{a}_1$  and  $\mathbf{a}_2$ , respectively and both are parallel to the vector  $\mathbf{b}$ , where BM is the shortest distance between  $l_1$  and  $l_2$ .

Let  $\theta$  be the angle between *AB* and  $l_1$ .

∴ Shortest distance between parallel lines

$$\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_1$$
 and  $\mathbf{r} = \mathbf{a}_2 + \mu \mathbf{b}$  is
$$d = \frac{|(\mathbf{a}_2 - \mathbf{a}_1) \times \mathbf{b}|}{|\mathbf{b}|}$$

**Example 35.** Show that the two lines

$$\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4}$$
 and  $\frac{x-4}{5} = \frac{y-1}{2} = z$ , intersect.

Also, find the point of intersection of these lines.

**Sol.** Here, 
$$\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4}$$
 ...(i) and  $\frac{x-4}{5} = \frac{y-1}{2} = \frac{z-0}{1}$  ...(ii)

Any point on line (i) is P(2r + 1, 3r + 2, 4r + 3) and any point on the line (ii) is  $Q(5\lambda + 4, 2\lambda + 1, \lambda)$ .

They intersect if and only if

$$2r + 1 = 5\lambda + 4$$
,  $3r + 2 = 2\lambda + 1$ ,  $4r + 3 = \lambda$ 

On solving,

$$r = -1$$
,  $\lambda = -1$ 

Clearly, for these values of  $\lambda$  and r P(-1, -1, -1)

Hence, lines (i) and (ii) intersect at (-1, -1, -1).

**Example 36.** Find the shortest distance between the lines  $\mathbf{r} = (4\hat{\mathbf{i}} - \hat{\mathbf{j}}) + \lambda (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 3\hat{\mathbf{k}})$  and  $\mathbf{r} = (\hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}) + \mu (2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}})$ .

**Sol.** We know, the shortest distance between the lines

$$\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_1$$
 and  $\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_2$ 

$$\Rightarrow \qquad d = \left| \frac{(\mathbf{a}_2 - \mathbf{a}_1) \cdot (\mathbf{b}_1 \times \mathbf{b}_2)}{|\mathbf{b}_1 \times \mathbf{b}_2|} \right|$$

On comparing the given equation with the equations  $\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_1 \text{ and } \mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_2 \text{ respectively, we have}$   $\mathbf{a}_1 = 4\hat{\mathbf{i}} - \hat{\mathbf{j}}, \mathbf{a}_2 = \hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}, \mathbf{b}_1 = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 3\hat{\mathbf{k}} \text{ and } \mathbf{b}_2 = 2\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 5\hat{\mathbf{k}}$  Now.  $\mathbf{a}_2 - \mathbf{a}_1 = -3\hat{\mathbf{i}} + 0\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ 

and 
$$\mathbf{b}_1 \times \mathbf{b}_2 = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1 & 2 & -3 \\ 2 & 4 & -5 \end{vmatrix} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 0\hat{\mathbf{k}}$$

$$\therefore (\mathbf{a}_2 - \mathbf{a}_1) \cdot (\mathbf{b}_1 \times \mathbf{b}_2) = (-3\hat{\mathbf{i}} + 0\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) \cdot (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 0\hat{\mathbf{k}}) = -6$$
and
$$|\mathbf{b}_1 \times \mathbf{b}_2| = \sqrt{4 + 1 + 0} = \sqrt{5}$$

$$\therefore \text{ Shortest distance, } d = \left| \frac{(\mathbf{a}_2 - \mathbf{a}_1) \cdot (\mathbf{b}_1 \times \mathbf{b}_2)}{|\mathbf{b}_1 \times \mathbf{b}_2|} \right| = \left| \frac{-6}{\sqrt{5}} \right| = \frac{6}{\sqrt{5}}$$

# Example 37. Find the shortest distance between the lines

**Sol.** Given lines are

Shortest distance between the lines (i) and (ii) are modulus of

$$= \frac{\begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix}}{\sqrt{(l_1 m_2 - l_2 m_1) + (m_1 n_2 - m_2 n_1)^2}} \dots (iii)$$

Now, = 
$$\begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = \begin{vmatrix} 1 & 2 & 2 \\ 2 & 3 & 4 \\ 3 & 4 & 5 \end{vmatrix}$$

Also, 
$$(l_1 m_2 - l_2 m_1)^2 + (m_1 n_2 - m_2 n_1)^2 + (n_1 l_2 - n_2 l_1)^2$$

$$\mathbf{r} = (-3\hat{\mathbf{i}} - 7\hat{\mathbf{j}} + 6\hat{\mathbf{k}}) + \mu (-3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}})$$

Sol. Given lines are

$$\mathbf{r} = (3\hat{\mathbf{i}} + 8\hat{\mathbf{j}} + 3\hat{\mathbf{k}}) + \lambda(3\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) \qquad \dots(i)$$

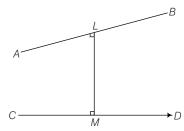

and 
$$\mathbf{r} = (-3\hat{\mathbf{i}} - 7\hat{\mathbf{j}} + 6\hat{\mathbf{k}}) + \mu(-3\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 4\hat{\mathbf{k}})$$
 ...(ii)

Equation of lines (i) and (iii) in cartesian form,

$$AB: \frac{x-3}{3} = \frac{y-8}{-1} = \frac{z-3}{1} = \lambda$$
 ...(iii)

and

CD: 
$$\frac{x+3}{-3} = \frac{y+7}{2} = \frac{z-6}{4} = \mu$$
 ...(iv)

Let 
$$L(3\lambda + 3)$$
,  $-\lambda + 8$ ,  $\lambda + 3$ ),  $M(-3\mu - 3, 2\mu - 7, 4\mu + 6)$ 

Direction ratios of *LM* are

$$(3\lambda + 3\mu + 6, -\lambda - 2\mu + 15, \lambda - 4\mu - 3)$$

Since,  $LM \perp AB$ 

$$\therefore 3(3\lambda + 3\mu + 6) - 1(-\lambda - 2\mu + 15) + 1(\lambda - 4\mu - 3) = 0$$
or
$$11\lambda + 7\mu = 0$$
...(v)

Again,  $LM \perp CD$ 

$$-3(3\lambda + 3\mu + 6) - 2(-\lambda - 2\mu + 15) + 4(\lambda - 4\mu - 3) = 0$$
$$-7\lambda - 29\mu = 0 \qquad \dots (vi)$$

Solving Eqs. (v) and (vi), we get

$$\lambda = 0 = \mu$$

$$L \equiv (3, 8, 3),$$

$$M \equiv (-3, -7, 6)$$

Hence, the shortest distance,

$$LM = \sqrt{(3+3)^2 + (8+7)^2 + (3-6)^2} = 3\sqrt{30}$$
 units

 $\therefore$  Vector equation of LM is

$$\mathbf{r} = 3\hat{\mathbf{i}} + 8\hat{\mathbf{j}} + 3\hat{\mathbf{k}} + t(6\hat{\mathbf{i}} + 15\hat{\mathbf{j}} - 3\hat{\mathbf{k}})$$

Also, the cartesian equation of LM is

$$\frac{x-3}{6} = \frac{y-8}{15} = \frac{z-3}{-3}$$

**Example 39.** Find the shortest distance between lines  $\mathbf{r} = (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + \hat{\mathbf{k}}) + \lambda (2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}})$ 

and 
$$\mathbf{r} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} - \hat{\mathbf{k}} + \mu(2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}).$$

**Sol.** Here lines (i) and (ii) are passing through the points  $\mathbf{a}_1 = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\mathbf{a}_2 = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} - \hat{\mathbf{k}}$ , respectively, and are parallel to the vector  $\mathbf{b} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ .

Hence, the distance between the lines using the formula

$$\frac{|\mathbf{b} \times (\mathbf{a}_{2} - \mathbf{a}_{1})|}{|\mathbf{b}|} = \frac{\begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & 1 & 2 \\ 1 & -3 & -2 \end{vmatrix}}{3}$$
$$= \frac{|4\hat{\mathbf{i}} - 6\hat{\mathbf{j}} - 7\hat{\mathbf{k}}|}{3} = \frac{\sqrt{16 + 36 + 49}}{3} = \sqrt{\frac{101}{3}}$$

**Example 40.** Find the equation of a line which passes through the point (1, 1, 1) and intersects the lines

$$\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4}$$
 and  $\frac{x+2}{1} = \frac{y-3}{2} = \frac{z+1}{4}$ .

**Sol.** Any line passing through the point (1, 1, 1) is

$$\frac{x-1}{a} = \frac{y-1}{b} = \frac{z-1}{c}$$
...(i)

This line intersects the line  $\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4}$ .

If 
$$a:b:c\neq 2:3:4$$
 and  $\begin{vmatrix} 1-1 & 2-1 & 3-1 \\ a & b & c \\ 2 & 3 & 4 \end{vmatrix} = 0$ 

$$\Rightarrow \qquad \qquad a-2b+c=0$$

Again, line (i) intersects line

$$\frac{x - (-2)}{1} = \frac{y - 3}{2} = \frac{z - (-1)}{4} \qquad \dots(ii)$$

If 
$$a:b:c \neq 1:2:4$$
 and  $\begin{vmatrix} -2-1 & 3-1 & -1-1 \\ a & b & c \\ 1 & 2 & 4 \end{vmatrix} = 0$ 

$$\Rightarrow 6a + 5b - 4c = 0 \qquad \dots(iii)$$

From (ii) and (iii) by cross multiplication, we have

$$\frac{a}{8-5} = \frac{b}{6+4} = \frac{c}{5+12}$$

$$\Rightarrow \qquad \frac{a}{3} = \frac{b}{10} = \frac{c}{17}$$

So, the required lines is  $\frac{x-1}{3} = \frac{y-1}{10} = \frac{z-1}{17}$ 

**Example 41.** If the straight lines x = -1 + s,

$$y = 3 - \lambda s$$
,  $z = 1 + \lambda s$  and  $x = \frac{t}{2}$ ,  $y = 1 + t$ ,  $z = 2 - t$ , with

parameters s and t, respectively, are coplanar, then find  $\lambda$ .

**Sol.** The given lines 
$$\frac{x+1}{1} = \frac{y-3}{\lambda} = \frac{z-1}{\lambda} = s$$

$$\frac{x-0}{y_2} = \frac{y-1}{1} = \frac{y-2}{-1} = t \text{ are coplanar if}$$

$$\begin{vmatrix} 0+1 & 1-3 & 2-1 \\ 1 & -\lambda & \lambda \\ 1/2 & 1 & -1 \end{vmatrix} = 0$$

$$\begin{vmatrix} 1 & -2 & 1 \\ 1 & -\lambda & \lambda \\ 1/2 & 1 & -1 \end{vmatrix} = 0$$

$$\Rightarrow 1(\lambda - \lambda) + 2\left(1 - \frac{\lambda}{2}\right) + 1\left(1 + \frac{\lambda}{2}\right) = 0$$

$$\Rightarrow \qquad \qquad \lambda = -$$

# Plane, Equation of Plane in Various Form, Angle between Two Planes, Family of Planes, Two Sides of a Plane, Distance of a Point from a Plane, Equation of Planes Bisecting the Angle between Two Planes, Line and Plane

## **Plane**

A plane is a surface such that if any two points are taken on it, the line segment joining them lies completely on the surface.

**General Form** General equation of the first degree in x, y, z always represents a plane.

The general equation of plane is ax + by + cz + d = 0.

**Proof.** Let first degree equation in x, y and z be

$$ax + by + cz + d = 0 \qquad \qquad \dots (i)$$

In order to prove that Eq. (i) is the equation of plane, it is sufficient to show that every point on the line joining two points lies on the surface represented by Eq. (i).

Let  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  be two points on the surface represented by Eq. (i).

Then, 
$$ax_1 + by_1 + cz_1 + d = 0$$
 ...(ii)

and 
$$ax_2 + by_2 + cz_2 + d = 0$$
 ...(iii)

Let *R* be any arbitrary point on the line segment joining *P* and *Q*. Suppose *R* divides *PQ* in the ratio  $\lambda$  :1.

$$\therefore R \text{ is } \left( \frac{x_1 + \lambda x_2}{1 + \lambda}, \frac{y_1 + \lambda y_2}{1 + \lambda}, \frac{z_1 + \lambda z_2}{1 + \lambda} \right)$$

We are to show that R lies on the surface represented by Eq. (i) for all values of  $\lambda$ . For this, it is sufficient to prove that R satisfy Eq. (i)

On putting this value of *R* in LHS of Eq. (i), we obtain

$$a\left(\frac{x_1 + \lambda x_2}{\lambda + 1}\right) + b\left(\frac{y_1 + \lambda y_2}{\lambda + 1}\right) + c\left(\frac{z_1 + \lambda z_2}{\lambda + 1}\right) + d$$

$$= \frac{1}{\lambda + 1} \left\{ (ax_1 + by_1 + cz_1) + \lambda (ax_2 + by_2 + cz_2) \right\}$$

$$= \frac{1}{\lambda + 1} [0 + 0] \qquad \text{[using Eqs. (ii) and (iii)]}$$

$$= 0$$

which shows that the point R lies on Eq. (i). Since, R is an arbitrary point on the line segment joining P and Q.

 $\therefore$  Every point on PQ lies on the surface represented by Eq. (i).

Hence, ax + by + cz + d = 0 is equation of plane.

#### Equation of a Plane Passing Through a Given Point

The general equation of a plane passing through a given point  $(x_1, y_1, z_1)$  is  $a(x - x_1) + b(y - y_1) + c(z - z_1) = 0$ , where a, b and c are constants.

**Proof.** The general equation of plane is

$$ax + by + cz + d = 0 \qquad \dots (i)$$

If it passes through  $(x_1, y_1, z_1)$ 

$$\Rightarrow \qquad ax_1 + by_1 + cz_1 + d = 0 \qquad \dots (ii)$$

On subtracting Eq. (i) from Eq. (ii), we get

$$a(x-x_1) + b(y-y_1) + c(z-z_1) = 0$$

which is the equation of a plane passing through  $(x_1, y_1, z_1)$ .

**Example 42.** Show that the four points (0, -1, -1), (-4, 4, 4), (4, 5, 1) and (3, 9, 4) are coplanar. Find the equation of the plane containing them.

**Sol.** We shall find the equation of a plane passing through any three out of the given four points and show that the fourth point satisfies the equation.

Now, any plane passing through (0, -1, -1) is

$$a(x-0) + b(y+1) + c(z+1) = 0$$
 ...(i)

If it passes through (-4, 4, 4), we have

$$a(-4) + b(5) + c(5) = 0$$
 ...(ii)

Also, if plane passes through (4, 5, 1), we have

$$a(4) + b(6) + c(2) = 0$$
  
 $2a + 3b + c = 0$  ...(iii)

On solving Eqs. (ii) and (iii) by cross multiplication method, we obtain

$$\frac{a}{-5} = \frac{b}{7} = \frac{c}{-11} = k$$

On putting in Eq. (i), we get

$$-5kx + 7k(y+1) - 11k(z+1) = 0$$

$$\Rightarrow -5x + 7y - 11z - 4 = 0$$

(required equation of plane)

Clearly, the fourth point namely (3, 9, 4) satisfies this equation. Hence, the given points are coplanar and the equation of plane containing those points, is 5x - 7y + 11z + 4 = 0

## **Equation of Plane** in Various Form

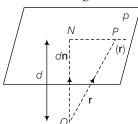

A plane is determined uniquely if

- (i) The normal to the plane and its distance from the origin is given, i.e. the equation of a plane in normal form.
- (ii) It passes through a point and is perpendicular to a given direction.
- (iii) It passes through three given non-collinear points.

## **Equation of Plane in Normal Form**

#### **Vector Form**

The vector equation of a plane normal to unit vector  $\hat{\bf n}$ and at a distance *d* from the origin is  $\mathbf{r} \cdot \hat{\mathbf{n}} = d$ .

**Proof.** Let *O* be the origin and let *ON* be the perpendicular from *O* to the given plane  $\pi$  such that  $\mathbf{ON} = d\hat{\mathbf{n}}$ , where *d* is perpendicular distance of plane from origin.

Let P be a point on the plane, with position vector  $\mathbf{r}$  so that OP = r

$\Rightarrow \qquad (\mathbf{OP} - \mathbf{ON}) \cdot \mathbf{ON} = 0$ $\Rightarrow \qquad (\mathbf{r} - d\hat{\mathbf{n}}) \cdot d\hat{\mathbf{n}} = 0$ $\Rightarrow \qquad \mathbf{r} \cdot d\hat{\mathbf{n}} - d^2  \hat{\mathbf{n}} \cdot \hat{\mathbf{n}} = 0$ $\Rightarrow \qquad d\mathbf{r} \cdot \hat{\mathbf{n}} - d^2   \mathbf{n} ^2 = 0 \qquad (\because d \neq 0)$ $\Rightarrow \qquad \mathbf{r} \cdot \hat{\mathbf{n}} - d = 0 \qquad (\because  \hat{\mathbf{n}}  = 0)$			
$\Rightarrow \qquad (\mathbf{OP} - \mathbf{ON}) \cdot \mathbf{ON} = 0$ $\Rightarrow \qquad (\mathbf{r} - d\hat{\mathbf{n}}) \cdot d\hat{\mathbf{n}} = 0$ $\Rightarrow \qquad \mathbf{r} \cdot d\hat{\mathbf{n}} - d^2 \hat{\mathbf{n}} \cdot \hat{\mathbf{n}} = 0$ $\Rightarrow \qquad d\mathbf{r} \cdot \hat{\mathbf{n}} - d^2  \mathbf{n} ^2 = 0 \qquad (\because d \neq 0)$ $\Rightarrow \qquad \mathbf{r} \cdot \hat{\mathbf{n}} - d = 0 \qquad (\because  \hat{\mathbf{n}}  = 0)$	Now,	$NP \perp ON$	
$\Rightarrow \qquad (\mathbf{r} - d\hat{\mathbf{n}}) \cdot d\hat{\mathbf{n}} = 0$ $\Rightarrow \qquad \mathbf{r} \cdot d\hat{\mathbf{n}} - d^2 \hat{\mathbf{n}} \cdot \hat{\mathbf{n}} = 0$ $\Rightarrow \qquad d\mathbf{r} \cdot \hat{\mathbf{n}} - d^2  \mathbf{n} ^2 = 0 \qquad (\because d \neq 0)$ $\Rightarrow \qquad \mathbf{r} \cdot \hat{\mathbf{n}} - d = 0 \qquad (\because  \hat{\mathbf{n}}  = 0)$	$\Rightarrow$	$\mathbf{NP} \cdot \mathbf{ON} = 0$	(i)
$\Rightarrow \qquad \mathbf{r} \cdot d\hat{\mathbf{n}} - d^2  \hat{\mathbf{n}} \cdot \hat{\mathbf{n}} = 0$ $\Rightarrow \qquad d\mathbf{r} \cdot \hat{\mathbf{n}} - d^2   \mathbf{n} ^2 = 0 \qquad (\because d \neq 0)$ $\Rightarrow \qquad \mathbf{r} \cdot \hat{\mathbf{n}} - d = 0 \qquad (\because  \hat{\mathbf{n}}  = 0)$	$\Rightarrow$	$(\mathbf{OP} - \mathbf{ON}) \cdot \mathbf{ON} = 0$	
$\Rightarrow d\mathbf{r} \cdot \hat{\mathbf{n}} - d^2  \mathbf{n} ^2 = 0 \qquad (\because d \neq 0)$ $\Rightarrow \mathbf{r} \cdot \hat{\mathbf{n}} - d = 0 \qquad (\because  \hat{\mathbf{n}}  = 0)$	$\Rightarrow$	$(\mathbf{r} - d\hat{\mathbf{n}}) \cdot d\hat{\mathbf{n}} = 0$	
$\Rightarrow \qquad \mathbf{r} \cdot \hat{\mathbf{n}} - d = 0 \qquad (\because  \hat{\mathbf{n}}  = 0)$	$\Rightarrow$	$\mathbf{r} \cdot d\hat{\mathbf{n}} - d^2 \hat{\mathbf{n}} \cdot \hat{\mathbf{n}} = 0$	
	$\Rightarrow$	$d\mathbf{r} \cdot \hat{\mathbf{n}} - d^2  \mathbf{n} ^2 = 0$	$(\because d \neq 0)$
	$\Rightarrow$	$\mathbf{r} \cdot \hat{\mathbf{n}} - d = 0$	$(\because \mid \hat{\mathbf{n}} \mid = 1)$
$\Rightarrow$ $\mathbf{r} \cdot \hat{\mathbf{n}} = d$	$\Rightarrow$	$\mathbf{r} \cdot \hat{\mathbf{n}} = d$	(ii)

Thus, the required equation of the plane is  $\mathbf{r} \cdot \hat{\mathbf{n}} = d$ .

#### **Cartesian Form**

Equation (ii) gives the vector equation of a plane, where  $\hat{\bf n}$ is the unit vector normal to the plane. Let P(x, y, z) be any point on the plane. Then

$$\mathbf{OP} = \mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$$

Let l, m and n be the direction cosines of  $\hat{\mathbf{n}}$ .

Then, 
$$\hat{\mathbf{n}} = (l\hat{\mathbf{i}} + m\hat{\mathbf{j}} + n\hat{\mathbf{k}})$$

Therefore, (ii) gives

$$(x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}) \cdot (l\hat{\mathbf{i}} + m\hat{\mathbf{j}} + n\hat{\mathbf{k}}) = d$$

$$lx + my + nz = d \qquad \dots(iii)$$

This is the cartesian equation of the plane in the normal form.

#### Note

or

Equation (iii) shows that if  $\mathbf{r} \cdot (a\hat{\mathbf{i}} + b\hat{\mathbf{j}} + c\hat{\mathbf{k}}) = d$  is the vector equation of a plane, then ax + by + cz = d is the cartesian equation of the plane, where a, b and c are the direction ratios of the normal to the plane.

The equation  $\mathbf{r} \cdot \mathbf{n} = d$  is in normal form, if  $\mathbf{n}$  is a unit vector and *d* is the distance of the plane from the origin. If **n** is not a unit vector, then to reduce the equation  $\mathbf{r} \cdot \mathbf{n} = d$ to normal form, we reduce the equation  $\mathbf{r} \cdot \mathbf{n} = d$  to normal form by dividing both sides by  $| \mathbf{n} |$ , we get

$$\frac{\mathbf{r} \cdot \mathbf{n}}{|\mathbf{n}|} = \frac{d}{|\mathbf{n}|} \Rightarrow \mathbf{r} \cdot \mathbf{n} = \frac{d}{|\mathbf{n}|} = p \text{ (distance from the origin)}$$

**Example 43.** Find the vector equation of plane which is at a distance of 8 units from the origin and which is normal to the vector  $2\mathbf{i} + \mathbf{j} + 2\mathbf{k}$ .

**Sol.** Here, d = 8 and  $n = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ 

$$\mathbf{n} = \frac{\mathbf{n}}{|\mathbf{n}|} = \frac{2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}}{\sqrt{2^2 + 1^2 + 2^2}} = \frac{2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}}{3}$$

Hence, the required equation of plane is,  $\mathbf{r} \cdot \mathbf{n} = d$ 

$$\Rightarrow \qquad \mathbf{r} \cdot \left( \frac{2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}}{3} \right) = 8$$

$$\Rightarrow \qquad \mathbf{r} \cdot (2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}) = 24$$

**Example 44.** Reduce the equation

 $\mathbf{r} \cdot (3\mathbf{i} - 4\mathbf{j} + 12\mathbf{k}) = 5$  to normal form and hence find the length of perpendicular from the origin to the plane.

**Sol.** The given equation of plane is

$$\mathbf{r} \cdot (3\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 12\hat{\mathbf{k}}) = 5 \text{ or } \mathbf{r} \cdot \mathbf{n} = 5$$

 $\mathbf{n} = 3\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 12\hat{\mathbf{k}}$ 

Since,  $|\mathbf{n}| = \sqrt{9 + 16 + 144} = 13 \neq 1$ , therefore the given equation is not the normal form. To reduce to normal form we divide both sides by  $|\mathbf{n}|$  i.e.  $\frac{\mathbf{r} \cdot \mathbf{n}}{|\mathbf{n}|} = \frac{5}{|\mathbf{n}|}$  or  $\mathbf{r} \cdot \left(\frac{3}{13}\hat{\mathbf{i}} - \frac{4}{13}\hat{\mathbf{j}} + \frac{12}{13}\hat{\mathbf{k}}\right) = \frac{5}{13}$ . This is the normal form of the equation of given plane and length perpendicular  $=\frac{5}{13}$ .

**Example 45.** Find the distance of the plane 2x - y - 2z - 9 = 0 from the origin.

**Sol.** The plane can be put in vector form as  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - \hat{\mathbf{j}} - 2\hat{\mathbf{k}}) = 9$ .

Here, 
$$\mathbf{n} = 2\hat{\mathbf{i}} - \hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$
  

$$\Rightarrow \frac{\mathbf{n}}{|\mathbf{n}|} = \frac{2\hat{\mathbf{i}} - \hat{\mathbf{j}} - 2\hat{\mathbf{k}}}{3}$$

Dividing equation throughout by 3, we have equation of plane in normal form as  $\mathbf{r} \cdot \frac{(2\hat{\mathbf{i}} - \hat{\mathbf{j}} - 2\hat{\mathbf{k}})}{3} = 3$ , in which 3 is the distance of the plane from the origin.

**Example 46.** Find the vector equation of a line passing through  $3\hat{\mathbf{i}} - 5\hat{\mathbf{j}} + 7\hat{\mathbf{k}}$  and perpendicular to the plane 3x - 4y + 5z = 8.

**Sol.** The given plane 3x - 4y + 5z = 8.

or 
$$(3\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 5\hat{\mathbf{k}})(x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}) = 8.$$

This shows that  $\mathbf{d} = 3\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$  is normal to the given plane.

Therefore, the required line is parallel to  $3\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 5\hat{\mathbf{k}}$ .

Since, the required line passes through  $3\hat{\bf i} - 5\hat{\bf j} + 7\hat{\bf k}$ , its equation is given by  ${\bf r} = 3\hat{\bf i} - 5\hat{\bf j} + 7\hat{\bf k} + \lambda(3\hat{\bf i} - 4\hat{\bf j} + 5\hat{\bf k})$ , where  $\lambda$  is a parameter.

**Example 47.** Find the unit vector perpendicular to the plane  $\mathbf{r} \cdot (2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}) = 5$ .

**Sol.** Vector normal to the plane is  $\mathbf{n} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ 

Hence, unit vector perpendicular to the plane is

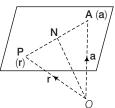

$$\frac{\mathbf{n}}{|\mathbf{n}|} = \frac{2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}}}{\sqrt{2^2 + 1^2 + 2^2}}$$
$$= \frac{1}{2} (2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 2\hat{\mathbf{k}})$$

#### Vector Equation of a Plane Passing Through a Given Point and Normal to a Given Vector

The vector equation of a plane passing through a point having position vector  $\mathbf{a}$  and normal to vector  $\mathbf{n}$  is  $(\mathbf{r} - \mathbf{a}) \cdot \mathbf{n} = 0$ .

**Proof** Suppose the planer  $\pi$  passes through a point having position vector  $\mathbf{a}$  and is normal to the vector  $\mathbf{n}$ . Let O be the origin and  $\mathbf{r}$  be the position vector of any point P on the plane  $\pi$ . Then,  $\mathbf{OP} = \mathbf{r}$ .

Since, AP lies in the plane and n is a normal to the plane  $\pi$ .

Hence, the required equation of the plane is

$$(\mathbf{r} - \mathbf{a}) \cdot \mathbf{n} = 0$$

#### Note

The above equation can be written as  $\mathbf{r} \cdot \mathbf{n} = d$ , where  $\mathbf{d} = \mathbf{a} \cdot \mathbf{n}$  (known as scalar product form of plane).

#### Cartesian Form

If 
$$\mathbf{r} = x\hat{\mathbf{i}} + y \hat{\mathbf{j}} + z\hat{\mathbf{k}}$$
,  $\mathbf{a} = x_1 \hat{\mathbf{i}} + y_1 \hat{\mathbf{j}} + z_1 \hat{\mathbf{k}}$  and  $\mathbf{n} = a\hat{\mathbf{i}} + b\hat{\mathbf{j}} + c\hat{\mathbf{k}}$ ,  
then  $(\mathbf{r} - \mathbf{a}) = (x - x_1)\hat{\mathbf{i}} + (y - y_1)\hat{\mathbf{j}} + (z - z_1)\hat{\mathbf{k}}$ 

Then equation of the plane can be written as

$$(x - x_1)\hat{\mathbf{i}} + (y - y_1)\hat{\mathbf{j}} + (z - z_1)\hat{\mathbf{k}} \cdot (a\hat{\mathbf{i}} + b\hat{\mathbf{j}} + c\hat{\mathbf{k}}) = 0$$

$$\Rightarrow a(x - x_1) + b(y - y_1) + c(z - z_1) = 0$$

Thus, the coefficients of x, y and z in the cartesian equation of a plane are the direction ratios of the normal to the plane.

**Example 48.** Find the equation of the plane passing through the point (2, 3, 1) having (5, 3, 2) as the direction ratios of the normal to the plane.

**Sol.** The equation of the plane passing through  $(x_1, y_1, z_1)$  and perpendicular to the line with direction ratios a, b and c is given by  $a(x - x_1) + b(y - y_1) + c(z - z_1) = 0$ .

Now, since the plane passes through (2, 3, 1) and is perpendicular to the line having direction ratios (5, 3, 2), the equation of the plane is given by 5(x-2) + 3(y-3) + 2(z-1) = 0 or 5x + 3y + 2z = 21.

**Example 49.** The foot of the perpendicular drawn from the origin to a plane is (12, -4, 3). Find the equation of the plane.

**Sol.** Since P(12, -4,3) is the foot of the perpendicular from the origin to the plane OP is normal to the plane  $\pi$ . Thus, the direction ratios of narmal to the plane are 12, -4 and 3. Now, since the plane passes through (12, -4, 3), its equation is given by

$$12(x-12) - 4(y+4) + 3(z-3) = 0$$
  
or 
$$12x - 4y + 3z - 169 = 0$$

...(i)

**Example 50.** A vector **n** of magnitude 8 units is inclined to X-axis at 45°, Y-axis at 60° and an acute angle with Z-axis. If a plane passes through a point  $(\sqrt{2}, -1, 1)$  and is normal to **n**, then find its equation in

**Sol.** Let  $\gamma$  be the angle made by  $\mathbf{n}$  with Z-axis, then direction cosines of n are

$$l = \cos 45^\circ = \frac{1}{\sqrt{2}}, m = \cos 60^\circ = \frac{1}{2} \text{ and } n = \cos \gamma$$

$$\therefore l^2 + m^2 + n^2 = 1 \Rightarrow \frac{1}{2} + \frac{1}{4} + n^2 = 1$$

$$\Rightarrow n^2 = \frac{1}{4}$$

$$n = \frac{1}{2} \text{ (neglecting } n = -\frac{1}{2} \text{ as } \gamma \text{ is acute : } n > 0\text{)}$$

We have, 
$$|\mathbf{n}| = 8$$
  
 $\mathbf{n} = |\mathbf{n}| (l\hat{\mathbf{i}} + m\hat{\mathbf{j}} + n\hat{\mathbf{k}})$   
 $\mathbf{n} = 8\left(\frac{1}{\sqrt{2}}\hat{\mathbf{i}} + \frac{1}{2}\hat{\mathbf{j}} + \frac{1}{2}\hat{\mathbf{k}}\right) = 4\sqrt{2}\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$ 

The required plane passes through the point  $(\sqrt{2}, -1, 1)$  having position vector

$$\mathbf{a} = \sqrt{2}\,\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}$$

So, its vector equation is  $(\mathbf{r} - \mathbf{a}) \cdot \mathbf{n} = 0$ 

$$\Rightarrow \hat{\mathbf{r}} \cdot \hat{\mathbf{n}} = \hat{\mathbf{a}} \cdot \hat{\mathbf{n}}$$

$$\Rightarrow \mathbf{r} \cdot (4\sqrt{2}\,\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) = (\sqrt{2}\,\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) \cdot (4\sqrt{2}\,\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}})$$

$$\Rightarrow \mathbf{r} \cdot (4\sqrt{2}\,\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) = 8$$

$$\Rightarrow \mathbf{r} \cdot (\sqrt{2}\,\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) = 2$$

**Example 51.** Find the equation of the plane such that image of point (1, 2, 3) in it is (-1, 0, 1).

**Sol.** Since, the image of A(1, 2, 3) in the plane is B(-1, 0, 1), the plane passes through the mid-point (0, 1, 2) of AB and is normal to the vector  $\mathbf{AB} = -2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$ .

Hence, the equation of the plane is -2(x-0)-2(y-1)

$$-2(z-2) = 0$$
or 
$$x + y + z = 3.$$

## **Equation of a Plane Passing through Three Given Points**

#### Cartesian Form

Let the plane be passing through points  $A(x_1, y_1, z_1)$ ,  $B(x_2, y_2, z_2)$  and  $C(x_3, y_3, z_3)$ .

Let P(x, y, z) be any point on the plane.

Then, vectors PA, BA and CA are coplanar.

$$[PA BA CA] = 0$$

$$\Rightarrow \begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ x_3 - x_1 & y_3 - y_1 & z_3 - z_1 \end{vmatrix} = 0, \text{ which is the required}$$

equation of the plane

#### **Vector Form**

Vector form of the equation of the plane passing through three points A, B and C having position vectors **a**, **b** and **c**, respectively.

Let  $\mathbf{r}$  be the position vector of any point P in the plane.

Hence, vector  $\mathbf{AP} = \mathbf{r} - \mathbf{a}$   $\mathbf{AB} = \mathbf{b} - \mathbf{a}$  and  $\mathbf{AC} = \mathbf{c} - \mathbf{a}$  are coplanar.

Hence, 
$$(\mathbf{r} - \mathbf{a}) \cdot \{(\mathbf{b} - \mathbf{a}) \times (\mathbf{c} - \mathbf{a})\} = 0$$
  
 $\Rightarrow \qquad (\mathbf{r} - \mathbf{a}) \cdot (\mathbf{b} \times \mathbf{c} - \mathbf{b} \times \mathbf{a} - \mathbf{a} \times \mathbf{c} + \mathbf{a} \times \mathbf{a}) = 0$   
 $\Rightarrow \qquad (\mathbf{r} - \mathbf{a}) \cdot (\mathbf{b} \times \mathbf{c} + \mathbf{a} \times \mathbf{b} + \mathbf{c} \times \mathbf{a}) = 0$   
 $\Rightarrow \qquad \mathbf{r} \cdot (\mathbf{b} \times \mathbf{c} + \mathbf{a} \times \mathbf{b} + \mathbf{c} \times \mathbf{a})$   
 $= \mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) + \mathbf{a} \cdot (\mathbf{a} \times \mathbf{b}) + \mathbf{a} \cdot (\mathbf{c} \times \mathbf{a})$   
 $\Rightarrow \qquad [\mathbf{r} \ \mathbf{b} \ \mathbf{c}] + [\mathbf{r} \ \mathbf{a} \ \mathbf{b}] + [\mathbf{r} \ \mathbf{c} \ \mathbf{a}] = [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]$ 

which is the required equation of the plane.

#### Note

- 1. If p is the length of perpendicular from the origin on this plane, then  $p = [\mathbf{a} \mathbf{b} \mathbf{c}] / n$ , where  $n = |\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a}|$ .
- 2. Four points a, b, c and d are coplanar if d lies on the plane containing a, b and c.

or 
$$\mathbf{d} \cdot [\mathbf{a} \times \mathbf{b} + \mathbf{b} \times \mathbf{c} + \mathbf{c} \times \mathbf{a}] = [\mathbf{a} \mathbf{b} \mathbf{c}]$$
or 
$$[\mathbf{d} \mathbf{a} \mathbf{b}] + [\mathbf{d} \mathbf{b} \mathbf{c}] + [\mathbf{d} \mathbf{c} \mathbf{a}] = [\mathbf{a} \mathbf{b} \mathbf{c}]$$

**Example 52.** Find the equation of the plane passing through A(2, 2, -1), B(3, 4, 2) and C(7, 0, 6). Also find a unit vector perpendicular to this plane.

**Sol.** Here, 
$$(x_1, y_1, z_1) \equiv (2, 2, -1), (x_2, y_2, z_2) \equiv (3, 4, 2)$$
 and  $(x_3, y_3, z_3) \equiv (7, 0, 6)$ .

Then, the equation of the plane is

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ x_3 - x_1 & y_3 - y_1 & z_3 - z_1 \end{vmatrix} = 0$$
or
$$\begin{vmatrix} x - 2 & y - 2 & z - (-1) \\ 3 - 2 & 4 - 2 & 2 - (-1) \\ 7 - 2 & 0 - 2 & 6 - (-1) \end{vmatrix} = 0$$
or
$$5x + 2y - 3z = 17$$

A normal vector to this plane is  $\mathbf{d} = 5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 3\hat{\mathbf{k}}$ 

Therefore, a unit vector normal to (i) is given by

$$\hat{\mathbf{n}} = \frac{\mathbf{d}}{|\mathbf{d}|} = \frac{5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 3\hat{\mathbf{k}}}{\sqrt{25 + 4 + 9}}$$
$$= \frac{1}{\sqrt{38}} (5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 3\hat{\mathbf{k}})$$

**Example 53.** Find equation of plane passing through the points P(1, 1, 1), Q(3, -1, 2) and R(-3, 5, -4).

**Sol.** Let the equation of plane passing through (1, 1, 1) be a(x-1)+b(y-1)+c(z-1)=0, as it passes through the points Q and R.

$$\therefore \qquad 2a - 2b + c = 0$$

and -4a + 4b - 5c = 0

Hence, solving by cross multiplication method, we get

$$\frac{a}{10-4} = \frac{b}{-4+10} = \frac{c}{8-8} = k$$

$$a = 6k, b = 6k, c = 0$$

On substituting in Eq. (i), we get

$$6(x-1) + 6(y-1) + 0 = 0$$

i.e. x + y = 2; which is the required equation.

**Aliter** Equation of plane passing through  $(x_1, y_1, z_1)$ ,  $(x_2, y_2, z_2)$  and  $(x_3, y_3, z_3)$  is

$$= \begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ x_3 - x_1 & y_3 - y_1 & z_3 - z_1 \end{vmatrix} = 0$$

$$| x - 1 \quad y - 1 \quad z - 1 |$$

i.e. 
$$\begin{vmatrix} x-1 & y-1 & z-1 \\ 3-1 & -1-1 & 2-1 \\ -3-1 & 5-1 & -4-1 \end{vmatrix} = 0$$

On solving, we get x + y = 2

# Equation of a Plane Passing Through a Given Point and Parallel to Two Given Vectors

Let a plane pass through  $A(\mathbf{a})$  and is parallel to the plane formed by two vectors  $\mathbf{b}$  and  $\mathbf{c}$ . Since,  $\mathbf{AP}$  lies in the plane and  $\mathbf{b}$  and  $\mathbf{c}$  are two non-collinear vectors,

$$\mathbf{AP} = \lambda \mathbf{b} + \mu \mathbf{c}$$

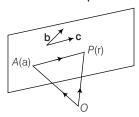

$$\mathbf{r} - \mathbf{a} = \lambda \mathbf{b} + \mu \mathbf{c}$$

 $\Rightarrow$ 

 $\Rightarrow$ 

or

$$\mathbf{r} = \mathbf{a} + \lambda \mathbf{b} + \mu \mathbf{c}$$

Here,  $\lambda$  and  $\mu$  are arbitrary scalars.

This form is also called the parametric form of the plane. It can also be written in the non-parametric form as

$$(\mathbf{r} - \mathbf{a}) \cdot (\mathbf{b} \times \mathbf{c}) = 0$$
  
 $[\mathbf{r} \ \mathbf{b} \ \mathbf{c}] = [\mathbf{a} \ \mathbf{b} \ \mathbf{c}]$ 

#### Cartesian Form

From  $(\mathbf{r} - \mathbf{a}) \cdot (\mathbf{b} \times \mathbf{c}) = 0$ , we have  $[\mathbf{r} - \mathbf{a} \mathbf{b} \mathbf{c}]$ 

$$\Rightarrow \begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ x_2 & y_2 & z_2 \\ x_3 & y_3 & z_3 \end{vmatrix} = 0, \text{ which is the required}$$

equation of the plane, where  $\mathbf{b} = x_2 \hat{\mathbf{i}} + y_2 \hat{\mathbf{j}} + z_2 \hat{\mathbf{k}}$  and  $\mathbf{c} = x_3 \hat{\mathbf{i}} + y_3 \hat{\mathbf{j}} + z_3 \hat{\mathbf{k}}$ .

**Example 54.** Find the vector equation of the following planes in cartesian form  $\mathbf{r} = \hat{\mathbf{i}} - \hat{\mathbf{j}} + \lambda(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) + \mu(\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})$ .

**Sol.** The equation of the plane is

$$\mathbf{r} = \hat{\mathbf{i}} - \hat{\mathbf{j}} + \lambda(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) + \mu(\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}).$$

Let 
$$\mathbf{r} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$$

Hence, the equation is

$$(x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}}) = \lambda(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) + \mu(\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}})$$

Thus, vectors  $(x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}) - (\hat{\mathbf{i}} - \hat{\mathbf{j}})$ ,  $\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$ ,  $\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  are coplanar.

Therefore, the equation of the plane is

$$\begin{vmatrix} x-1 & y-(-1) & z-0 \\ 1 & 1 & 1 \\ 1 & -2 & 3 \end{vmatrix} = 0$$

$$5x-2y-3z-7=0$$

#### Intercept Form of a Plane

The equation of a plane having intercepting lengths a, b and c with X-axis, Y-axis and Z-axis, respectively is

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$$

**Proof** Let *O* be the origin and let *OX*, *OY* and *OZ* be the coordinate axes.

Let the plane meets the coordinate axes at the points P, Q and R, respectively such that

OP = a, OQ = b and P = c. Then, the coordinates of the points are P(a, 0, 0), Q(0, b, 0) and R(0, 0, c).

Let the equation of plane be

$$Ax + By + Cz + D = 0 \qquad ...(i)$$

Since, Eq. (i) passes through (a, 0, 0), (0, b, 0) and (0, 0, c), we have

$$Aa + D = 0 \implies A = \frac{-D}{a}$$

$$Bb + D = 0 \implies B = \frac{-D}{b}$$

$$Cc + D = 0 \Rightarrow C = \frac{-D}{b}$$

On putting these values in Eq. (i),we get required equation of plane as

$$\frac{-D}{a}x - \frac{D}{b}y - \frac{D}{c}z = -D$$

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$$

**Example 55.** A plane meets the coordinates axes in A, B and C such that the centroid of the  $\triangle ABC$  is the point (p, q, r), show that the equation of the plane is  $\frac{x}{p} + \frac{y}{q} + \frac{z}{r} = 3$ 

**Sol.** Let the required equation of plane be

 $\Rightarrow$ 

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1 \qquad \dots (i$$

Then, the coordinates of A, B and C are A(a, 0, 0), B(0, b, 0) and C(0, 0, c), respectively. So, the centroid of the  $\triangle ABC$ ,

$$\left(\frac{a}{3}, \frac{b}{3}, \frac{c}{3}\right)$$

But the coordinate of the centroid are (p, q, r)

$$\frac{a}{3} = p, \frac{b}{3} = q, \frac{c}{3} = r$$

On putting the values of a, b and c in Eq. (i), we get

The required plane as

$$\frac{x}{3p} + \frac{y}{3q} + \frac{z}{3r} = 1$$

$$\Rightarrow \frac{x}{p} + \frac{y}{q} + \frac{z}{r} = 3$$

**Example 56.** A variable plane moves in such a way that the sum of the reciprocals of its intercepts on the three coordinate axes is constant. Show that the plane passes through the fixed point.

**Sol.** Let the equation of the plane be  $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ . Then, the

intercepts made by the plane with axes are a, b and c.

$$\therefore \frac{1}{a} + \frac{1}{b} + \frac{1}{c} = \text{constant}(k) \qquad \dots \text{(i) (given)}$$

$$\Rightarrow \frac{1}{ak} + \frac{1}{bk} + \frac{1}{ck} = 1$$
 comparing with  $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ 

$$x = \frac{1}{k}, y = \frac{1}{k}$$

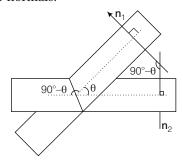

and z

This shows Eq. (i) passes through the fixed point  $\left(\frac{1}{k'}, \frac{1}{k'}, \frac{1}{k'}\right)$ .

## **Angle between Two Planes**

#### **Vector Form**

The angle between two planes is defined as the angle between their normals.

Let  $\theta$  be the angle between planes  $\mathbf{r} \cdot \mathbf{n}_1 = d_1$  and

$$\mathbf{r} \cdot \mathbf{n}_2 = d_2 \text{ then } \cos \theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{|\mathbf{n}_1| |\mathbf{n}_2|}$$

### **Condition for Perpendicularity**

If the planes  $\mathbf{r} \cdot \mathbf{n}_1 = d_1$  and  $\mathbf{r} \cdot \mathbf{n}_2 = \mathbf{d}_2$  are perpendicular, then  $\mathbf{n}_1$  and  $\mathbf{n}_2$  are perpendicular. Therefore,  $\mathbf{n}_1 \cdot \mathbf{n}_2 = 0$ 

#### **Condition for Parallelism**

If the planes  $\mathbf{r} \cdot \mathbf{n}_1 = d_1$  and  $\mathbf{r} \cdot \mathbf{n}_2 = d_2$  are parallel, there exists the scalar  $\lambda$  such that  $\mathbf{n}_1 = \lambda \mathbf{n}_2$ .

#### Cartesian Form

If the planes are  $a_1x + b_1y + c_1z + d = 0$ 

and 
$$a_2 x + b_2 y + c_2 z + d_2 = 0$$

$$\Rightarrow \qquad \cos \theta = \frac{a_1 a_2 + b_1 b_2 + c_1 c_2}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}}$$

Condition for parallelism

$$\frac{a_1}{a_2} = \frac{b_1}{b_2} = \frac{c_1}{c_2} = \lambda$$

Condition for perpendicularity

$$a_1a_2 + b_1b_2 + c_1c_2 = 0$$

**Example 57.** Find the angle between the planes 2x + y - 2x + 3 = 0 and  $\mathbf{r} \cdot (6\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) = 5$ .

**Sol.** Normals along the given planes are  $2\hat{\bf i} + \hat{\bf j} - 2\hat{\bf k}$  and  $6\hat{\bf i} + 3\hat{\bf j} + 2\hat{\bf k}$ 

Then angle between planes,

$$\theta = \cos^{-1} \frac{(2\hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}}) \cdot (6\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 2\hat{\mathbf{k}})}{\sqrt{(2)^2 + (1)^2 + (-2)^2} \sqrt{(6)^2 + (3)^2 + (2)^2}} = \cos^{-1} \frac{11}{21}$$

#### **Example 58.** Show that ax + by + r = 0,

by + cz + p = 0 and cz + ax + q = 0 are perpendicular to XY, YZ and ZX planes, respectively.

**Sol.** The planes  $a_1x + b_1y + c_1z + d_1 = 0$  and

 $a_2x + b_2y + c_2z + d_2 = 0$  are perpendicular to each other if and only if  $a_1a_2 + b_1b_2 + c_1c_2 = 0$ .

The equation of XY, YZ and ZX planes are z = 0, x = 0 and y = 0, respectively.

Now, we have to show that z = 0 is perpendicular to

$$ax + by + r = 0$$
.

It follows immediately, since a(0) + b(0) + (0)(1) = 0, other parts can be done similarly.

## **Family of Planes**

### Plane Parallel to a Given Plane

Since parallel planes have the same normal vector, so equation of a plane parallel to  $\mathbf{r} \cdot \mathbf{n} = d_1$  is of the form  $\mathbf{r} \cdot \mathbf{n} = d_2$ , where  $d_2$  is determined by the given conditions. In cartesian form, if ax + by + cz + d = 0 be the given plane

then the plane parallel to this plane is ax + by + cz + k = 0.

**Example 59.** Find the equation of the plane through the point (1, 4, -2) and parallel to the plane -2x + y - 3z = 7.

**Sol.** Let the equation of a plane parallel to the plane -2x + y - 3z = 7 be

$$-2x + y - 3z + k = 0$$
 ...(i)

This passes through (1, 4, -2), therefore

$$(-2)(1) + 4 - 3(-2) + k = 0$$
  
 $-2 + 4 + 6 + k = 0 \implies k = -8$ 

Putting k = -8 in Eq. (i), we obtain

$$-2x + y - 3z - 8 = 0$$
 or  $-2x + y - 3z = 8$ 

This is the equation of the required plane.

**Example 60.** Find the equation of the plane passing through (3, 4, -1), which is parallel to the plane  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 5\hat{\mathbf{k}}) + 7 = 0$ .

**Sol.** The equation of any plane which is parallel to  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 5\hat{\mathbf{k}}) + 7 = 0$  is

$$\mathbf{r} \cdot (2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 5\hat{\mathbf{k}}) + \lambda = 0$$

$$2x - 3y + 5z + \lambda = 0$$

Further (i) will pass through (3, 4, -1)

if (2) (3) + (-3) (4) + 5(-1) + 
$$\lambda$$
 = 0

or 
$$-11 + \lambda = 0 \Rightarrow \lambda = 11$$

Thus, equation of the required plane is

$$\mathbf{r} \cdot (2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 5\hat{\mathbf{k}}) + 11 = 0$$

## Equation of any Plane Passing Through the Line of Intersection of Two Plane

The equation of the plane passing through the line of intersection of the planes

$$a_1x + b_1y + c_1z + d_1 = 0$$
 and  $a_2x + b_2y + c_2z + d_2 = 0$  is  $(a_1x + b_1y + c_1z + d_1) + k(a_2x + b_2y + c_2z + d_2) = 0$ 

**Proof** Let the given plane be

$$a_1x + b_1y + c_1z + d_1 = 0$$
 ...(i)

and  $a_2x + b_2y + c_2z + d_2 = 0$  ...(ii)

 $\therefore$  Required plane is  $(a_1x + b_1y + c_1z + d_1)$ 

$$+k(a_2x + b_2y + c_2z + d_2) = 0$$
 ...(iii)

Clearly, plane (iii) represents the equation of plane.

Let  $(\alpha, \beta, \gamma)$  be a point on the line of intersection of planes (i) and (ii), then *P* lies on planes (i) and (ii).

$$a_1 \alpha + b_1 \beta + c_1 \gamma + d_1 = 0 \qquad ...(iv)$$

and 
$$a_2\alpha + b_2\beta + c_2\gamma + d_2 = 0$$
 ...(v)

Now, multiply by k in plane (v) and then adding planes (iv) and (v), we get

$$(a_1\alpha + b_1\beta + c_1\gamma + d_1) + k(a_2\alpha + b_2\beta + c_2\gamma + d_2) = 0$$

 $\Rightarrow$   $P(\alpha, \beta, \gamma)$  lies on plane (iii).

Hence, plane (iii) passes through each point on the line of intersection of planes (i) and (ii).

Thus, plane (iii) is the equation of plane passing through the line of intersection of planes (i) and (ii).

#### **Vector Form**

Equation of planes passing through the line of intersection of planes

$$\mathbf{r} \cdot \mathbf{n}_1 = d_1$$
 and  $\mathbf{r} \cdot \mathbf{n}_2 = d_2$  is

$$(\mathbf{r} \cdot \mathbf{n}_1 - d_1) + k(\mathbf{r} \cdot \mathbf{n}_2 - d_2) = 0$$

or 
$$\mathbf{r} \cdot (\mathbf{n}_1 + k\mathbf{n}_2) = d_1 + kd_2$$
, *k* being any scalar.

**Example 61.** Find the equation of the plane containing the line of intersection of the plane x + y + z - 6 = 0 and 2x + 3y + 4z + 5 = 0 and passing through the points (1,1,1).

**Sol.** The equation of a plane through the line of intersection of the given plane is

$$(x + y + z - 6) + \lambda(2x + 3y + 4z + 5) = 0$$
 ...(i)

If line (i) passes through (1, 1, 1), we have

$$-3+14\lambda=0$$

$$\Rightarrow$$
  $\lambda = \frac{3}{14}$ 

Putting  $\lambda = \frac{3}{14}$  in line (i), we obtain the equation of the required plane as

$$(x+y+z-6) + \frac{3}{14}(2x+3y+4z+5) = 0$$
$$20x+23y+26z-69 = 0$$

**Example 62.** Find the planes passing through the intersection of planes  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) = 1$  and  $\mathbf{r} \cdot (\hat{\mathbf{i}} - \hat{\mathbf{j}}) + 4 = 0$  and perpendicular to planes  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) = -8$ .

**Sol.** The equation of any plane through the line of intersection of the given planes is

$$\begin{aligned} \{\mathbf{r} \cdot (2\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}) - 1\} + \lambda \{\mathbf{r} \cdot (\hat{\mathbf{i}} - \hat{\mathbf{j}}) + 4\} &= 0 \\ \mathbf{r} \cdot \{(2 + \lambda)\hat{\mathbf{i}} - (3 + \lambda)\hat{\mathbf{j}} + 4\hat{\mathbf{k}}\} &= 1 - 4\lambda \end{aligned} \dots (i$$

If it is perpendicular to  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) + 8 = 0$ , then

$$\{(2+\lambda)\hat{\mathbf{i}} - (3+\lambda)\hat{\mathbf{j}} + 4\hat{\mathbf{k}}\}\cdot(2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) = 0$$
$$2(2+\lambda) + (3+\lambda) + 4 = 0$$

$$\lambda = \frac{-11}{3}$$

Putting  $\lambda = -\frac{11}{3}$  in line (i), we obtain the equation of the required plane as  $\mathbf{r} \cdot (-5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 12\hat{\mathbf{k}}) = 47$ 

## Two Sides of a Plane

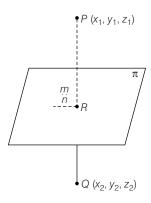

Let ax + by + cz + d = 0 be the plane, then the points  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  lie on the same side or opposite side according as

$$\frac{ax_1 + by_1 + cz_1 + d}{ax_2 + by_2 + cz_2 + d} > 0 \text{ or } < 0$$

**Proof** Here equation of plane is,

$$ax + by + cz + d = 0 \qquad \qquad \dots (i)$$

Let Eq. (i) divide the line segment joining P and Q at R internally in the ratio m:n.

Then, 
$$R\left(\frac{mx_2 + nx_1}{m+n}, \frac{my + ny_1}{m+n}, \frac{mz_2 + nz_1}{m+n}\right)$$

Since, R lies on the plane (i).

$$\therefore a \left( \frac{mx_2 + nx_1}{m+n} \right) + b \left( \frac{my_2 + ny_1}{m+n} \right) + c \left( \frac{mz_2 + nz_1}{m+n} \right) + d = 0$$

$$\Rightarrow a(mx_2 + nx_1) + b(my_2 + ny_1)$$

$$+c(mz_2 + nz_1) + d(m+n) = 0$$

$$\Rightarrow m(ax_2 + by_2 + cz_2 + d)$$

$$+ n(ax_1 + by_1 + cz_1 + d) = 0$$

$$\Rightarrow \frac{m}{n} = -\frac{(ax_1 + by_1 + cz_1 + d)}{(ax_2 + by_2 + cz_2 + d)} \qquad ...(ii)$$

Now, if  $ax_1 + by_1 + cz_1 + d$  and  $ax_2 + by_2 + cz_2 + d$ 

are of same sign 
$$\frac{m}{n} < 0$$
 (external division)

are of opposite sign  $\frac{m}{n} > 0$  (internal division)

:. If 
$$\frac{ax_1 + by_1 + cz_1 + d}{ax_2 + by_2 + cz_2 + d} > 0$$
 (same side)

$$\frac{ax_1 + by_1 + cz_1 + d}{ax_2 + by_2 + cz_2 + d} < 0$$
 (opposite side)

**Example 63.** Find the interval of  $\alpha$  for which  $(\alpha, \alpha^2, \alpha)$  and (3, 2, 1) lies on same side of

$$x + y - 4z + 2 = 0$$
.

**Sol.**  $(\alpha, \alpha^2, \alpha)$  and (3, 2, 1) lies on same side of x + y - 4z + 2 = 0

$$(\alpha + \alpha^2 - 4\alpha + 2)(3 + 2 - 4 + 2) > 0$$

$$\Rightarrow$$
  $\alpha^2 - 3\alpha + 2 > 0$ 

$$(\alpha -1)(\alpha -2) > 0 \Rightarrow \alpha \in (-\infty, 1] \cup (2, \infty]$$

## Distance of a Point from a Plane

#### **Vector Form**

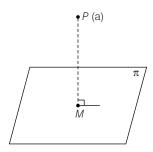

The length of the perpendicular from a point having position vector **a** to the plane  $\mathbf{r} \cdot \mathbf{n} = d$  is given by

$$P = \frac{|\mathbf{a} \cdot \mathbf{n} - d|}{|\mathbf{n}|}$$

**Proof.** Let  $\pi$  be the given plane and  $P(\mathbf{a})$  be the given point. Let PM be the length of perpendicular from P to the plane  $\pi$ .

Since, line *PM* passes through  $P(\mathbf{a})$  and is parallel to the vector  $\mathbf{n}$  which is normal to the plane  $\pi$ . So, vector equation of line *PM* is

$$\mathbf{r} = \mathbf{a} + \lambda \mathbf{n}$$
 ...(i)

Point M is the intersection of Eq. (i) and the given plane  $\pi$ .

$$\therefore \qquad (\mathbf{a} + \lambda \mathbf{n}) \cdot \mathbf{n} = d$$

$$\Rightarrow \mathbf{a} \cdot \mathbf{n} + \lambda \mathbf{n} \cdot \mathbf{n} = d \Rightarrow \lambda = \frac{d - (\mathbf{a} \cdot \mathbf{n})}{|\mathbf{n}|^2}$$

On putting the value of  $\lambda$  in Eq. (i), we obtain the position vector of M given by

$$\mathbf{r} = \mathbf{a} + \left(\frac{d - \mathbf{a} \cdot \mathbf{n}}{|\mathbf{n}|^2}\right) \mathbf{n}$$

PM = Position vector of M - Position vector of P

$$= \mathbf{a} + \left(\frac{d - (\mathbf{a} \cdot \mathbf{n})}{|\mathbf{n}|^2}\right) \mathbf{n} - \mathbf{a}$$

$$\mathbf{PM} = \left(\frac{d - (\mathbf{a} \cdot \mathbf{n})}{|\mathbf{n}|^2}\right) \mathbf{n}$$

$$\Rightarrow PM = |\mathbf{PM}| = \left|\frac{(d - \mathbf{a} \cdot \mathbf{n}) \mathbf{n}}{|\mathbf{n}|^2}\right|$$

$$= \frac{|d - (\mathbf{a} \cdot \mathbf{n})| |\mathbf{n}|}{|\mathbf{n}|^2} = \frac{|d - (\mathbf{a} \cdot \mathbf{n})|}{|\mathbf{n}|}$$

Thus, the length of perpendicular from a point having position vector **a** on the plane  $\mathbf{r} \cdot \mathbf{n} = d$  is  $\frac{|\mathbf{a} \cdot \mathbf{n} - d|}{|\mathbf{n}|}$ 

#### Cartesian Form

The length of perpendicular from a point  $P(x_1, y_1, z_1)$  to the plane ax + by + cz + d = 0. Then, the equation of PM is

$$\frac{x - x_1}{a} = \frac{y - y_1}{b} = \frac{z - z_1}{c}$$
 ...(i)

The coordinates of any point on this line are

$$(x_1 + ar, y_1 + br, z_1 + cr)$$

Thus, the point coincides with *M* iff it lies on plane.

i.e. 
$$a(x_1 + ar) + b(y_1 + br) + c(z_1 + cr) + d = 0$$

i.e. 
$$r = -\frac{(ax_1 + by_1 + cz_1 + d)}{a^2 + b^2 + c^2}$$
 ...(ii)

Now, 
$$PM = \sqrt{(x_1 + ar - x_1)^2 + (y_1 + br - y_1)^2 + (z_1 + cr - z_1)^2}$$

$$= \sqrt{(a^2 + b^2 + c^2) r^2} = \sqrt{a^2 + b^2 + c^2} |r|$$

$$= \sqrt{a^2 + b^2 + c^2} \left| \frac{-(ax_1 + by_1 + cz_1 + d)}{a^2 + b^2 + c^2} \right|$$

[from Eq. (ii)]

$$\therefore PM = \frac{|(ax_1 + by_1 + cz_1 + d)|}{\sqrt{a^2 + b^2 + c^2}}$$

**Example 64.** Find the distance of the point (2, 1, 0) from the plane 2x + y + 2z + 5 = 0.

**Sol.** We know that the distance of the point  $(x_1, y_1, z_1)$  from the plane ax + by + cz + d = 0 is

$$\frac{|ax_1 + by_1 + cz_1 + d|}{\sqrt{a^2 + b^2 + c^2}}$$

So, required distance = 
$$\frac{|2 \times 2 + 1 + 2 \times 0 + 5|}{\sqrt{2^2 + 1^2 + 2^2}} = \frac{10}{3}.$$

## Distance between the Parallel Planes

The distance between two parallel planes

$$ax + by + cz + d_1 = 0$$

and  $ax + by + cz + d_2 = 0$ 

is given by

$$d = \frac{(d_2 - d_1)}{\sqrt{a^2 + b^2 + c^2}}$$

**Proof.** Let d = Difference of the length of perpendicular from origin to the two planes.

$$= \frac{|d_1|}{\sqrt{a^2 + b^2 + c^2}} - \frac{|d_2|}{\sqrt{a^2 + b^2 + c^2}}.$$

if  $d_1$  and  $d_2$  are of same side =  $\frac{d_1 - d_2}{\sqrt{a^2 + b^2 + c^2}}$ 

#### **Vector Form**

The distance between two parallel plane  $\mathbf{r} \cdot \mathbf{n} = d_1$ 

and 
$$\mathbf{r} \cdot \mathbf{n} = d_2$$
 is given by

$$d = \frac{|d_1 - d_2|}{|\mathbf{n}|}$$

**Example 65.** Find the distance between the parallel planes x+2y-2z+1=0 and 2x+4y-4z+5=0.

**Sol.** We know that, distance between parallel planes  $ax + by + cz + d_1 = 0$  and  $ax + by + cz + d_2 = 0$  is,

$$\frac{|d_1 - d_2|}{\sqrt{a^2 + b^2 + c^2}}$$

∴ Distance between 
$$x + 2y - 2z + 1 = 0$$
  
and  $x + 2y - 2z + \frac{5}{2} = 0$  is 
$$\frac{\left|\frac{5}{2} - 1\right|}{\sqrt{1 + 4 + 4}} = \frac{1}{2}$$

# **Equation of Planes Bisecting the Angle between Two Planes**

Equation of the planes bisecting the angle between the planes.

$$a_1x + b_1y + c_1z + d_1 = 0 \text{ and } a_2x + b_2y + c_2z + d_2 = 0 \text{ is}$$

$$\frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} = \pm \frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}}$$

**Proof.** Given planes are

$$a_1x + b_1y + c_1z + d_1 = 0$$
 ...(i)  
 $a_2x + b_2y + c_2z + d_2 = 0$  ...(ii)

Let P(x, y, z) be a point on the plane bisecting the angle between planes (i) and (ii).

Let *PL* and *PM* be the length of perpendiculars from *P* to planes (i) and (ii).

$$\therefore PL = PM$$

$$\Rightarrow \left| \frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} \right| = \left| \frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}} \right|$$

$$\frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} = \pm \frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}}$$

This is equation of planes bisecting the angles between the planes (i) and (ii).

#### Vector Form

Equation of planes bisecting the angle between planes

$$\mathbf{r} \cdot \mathbf{n}_1 = d_1$$
 and  $\mathbf{r} \cdot \mathbf{n}_2 = d_2$  are

$$\begin{vmatrix} \mathbf{r} \cdot \mathbf{n}_1 - d_1 \\ \mathbf{n}_1 \end{vmatrix} = \begin{vmatrix} \mathbf{r} \cdot \mathbf{n}_2 - d_2 \\ \mathbf{n}_2 \end{vmatrix}$$

$$\Rightarrow \frac{\mathbf{r} \cdot \mathbf{n}_1 - d_1}{\mathbf{n}_1} = \pm \frac{\mathbf{r} \cdot \mathbf{n}_2 - d_2}{\mathbf{n}_2}$$

$$\Rightarrow \mathbf{r} \cdot \frac{\mathbf{n}_1}{|\mathbf{n}_1|} \pm \mathbf{r} \cdot \frac{\mathbf{n}_2}{|\mathbf{n}_1|} = \frac{d_1}{|\mathbf{n}_1|} \pm \frac{d_2}{|\mathbf{n}_2|}$$

$$\Rightarrow \mathbf{r} \cdot (\hat{\mathbf{n}}_1 \pm \hat{\mathbf{n}}_2) = \frac{d_1}{|\mathbf{n}_1|} \pm \frac{d_2}{|\mathbf{n}_2|}$$

## Bisector of the Angle between the Two Planes Containing the Origin

Let the equation of the two planes be

$$a_1x + b_1y + c_1z + d_1 = 0$$
 ...(i)

and 
$$a_2x + b_2y + c_2z + d_2 = 0$$
 ...(ii)

where,  $d_1$  and  $d_2$  are positive, then equation of the bisector of the angle between the planes (i) and (ii) containing the origin is

$$\frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} = \frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}}$$

## Bisector of the Acute and Obtuse Angles between Two Planes

Let the two planes be

$$a_1x + b_1y + c_1z + d_1 = 0$$
 ...(i)

and  $a_2x + b_2y + c_2z + d_2 = 0$  ...(ii)

where,  $d_1$  and  $d_2 > 0$ 

(a) If  $a_1a_2 + b_1b_2 + c_1c_2 > 0$ , the origin lies in the obtuse angle between the two planes and the equation of bisector of the acute angle is,

$$\frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} = -\frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}}$$

(b) If  $a_1a_2 + b_1b_2 + c_1c_2 < 0$ , then origin lies in the acute angle between the two planes and the equation of bisector of the acute angle between two planes is

$$\frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} = + \frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}}$$

**Example 66.** Find the equation of the bisector planes of the angles between the planes 2x - y + 2z + 3 = 0 and 3x - 2y + 6z + 8 = 0 and specify the plane which bisects the acute angle and the plane which bisects the obtuse angle.

**Sol.** The two given planes are

$$2x - y + 2z + 3 = 0 \text{ and } 3x - 2y + 6z + 8 = 0$$
where,  $d_1$  and  $d_2 > 0$ 
and
$$a_1a_2 + b_1b_2 + c_1c_2 = 6 + 2 + 12 > 0$$

$$\therefore \frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} = -\frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}}$$

(obtuse angle bisector)

and 
$$\frac{a_1x + b_1y + c_1z + d_1}{\sqrt{a_1^2 + b_1^2 + c_1^2}} = \frac{a_2x + b_2y + c_2z + d_2}{\sqrt{a_2^2 + b_2^2 + c_2^2}}$$

(acute angle bisector)

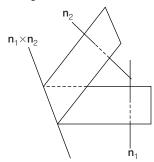

i.e. 
$$\frac{2x-y+2z+3}{\sqrt{4+1+4}} = \pm \frac{3x-2y+6z+8}{\sqrt{9+4+36}}$$

$$\Rightarrow (14x-7y+14z+21) = \pm (9x-6y+18z+24)$$
Taking positive sign on the right hand side, we get
$$5x-y-4z-3=0 \text{ (obtuse angle bisector)}$$
and taking negative sign on the right hand side, we get
$$23x-13y+32z+45=0 \text{ (acute angle bisector)}$$

## **Line and Plane**

## Line of Intersection of Two Planes

Let two non-parallel planes are  $\mathbf{r} \cdot \mathbf{n}_1 = d_1$  and  $\mathbf{r} \cdot \mathbf{n}_2 = d_2$ 

Now line of intersection of planes is perpendicular to vector  $\mathbf{n}_1$  and  $\mathbf{n}_2$ .

 $\therefore$  Line of intersection is parallel to vector  $\mathbf{n}_1 \times \mathbf{n}_2$ .

If we wish to find the equation of line of intersection of planes  $a_1x + b_1y + c_1z - d_1 = 0$  and  $a_2x + b_2y + c_2z - d_2 = 0$ , then we find any point on the line by putting z = 0 (say), then we can find corresponding values of x and y be solving equations  $a_1x + b_1y - d_1 = 0$  and  $a_2x + b_2y - d_2 = 0$ . Thus, by fixing the value of  $z = \lambda$ , we can find the corresponding value of x and y in terms of x. After getting x, y and z in terms of x, we can find the equation of line in symmetric form.

**Example 67.** Reduce the equation of line x - y + 2z = 5 and 3x + y + z = 6 in symmetrical form. Or

Find the line of intersection of planes x - y + 2z = 5 and 3x + y + z = 6.

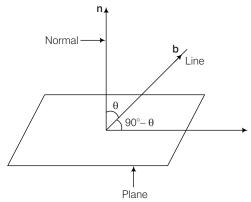

**Sol.** Given 
$$x - y + 2z = 5$$
,  $3x + y + z = 6$ .

Let 
$$z = \lambda$$
  
Then,  $x - y = 5 - 2\lambda$   
and  $3x + y = 6 - \lambda$ .

Solving these two equations,  $4x = 11 - 3\lambda$ 

and 
$$4y = 4x - 20 + 8\lambda = -9 + 5\lambda$$
 The equation of the line is 
$$\frac{4x - 11}{-3} = \frac{4y + 9}{5} = \frac{z - 0}{1}.$$

## Angle between a Line and a Plane

The angle between a line and a plane is the complement of the angle between the line and the normal to the plane. If the equation of the line is  $\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$  and that of the plane is  $\mathbf{r} \cdot \mathbf{n} = d$ , then angle  $\theta$  between the line and the

normal to the plane is 
$$\cos \theta = \left| \frac{\mathbf{b} \cdot \mathbf{n}}{|\mathbf{b}| |\mathbf{n}|} \right|$$

So, the angle  $\phi$  between the line and the plane is given by  $90^{\circ} - \theta$ .

$$\sin \phi = \left| \frac{\mathbf{b} \cdot \mathbf{n}}{|\mathbf{b}| |\mathbf{n}|} \right| \text{ or } \phi = \sin^{-1} \left| \frac{\mathbf{b} \cdot \mathbf{n}}{|\mathbf{b}| |\mathbf{n}|} \right|$$

Line  $\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$  and plane  $\mathbf{r} \cdot \mathbf{n} = d$  are perpendicular if  $\mathbf{b} = \lambda \mathbf{n}$  or  $\mathbf{b} \times \mathbf{n} = \mathbf{0}$  and parallel if  $\mathbf{b} \perp \mathbf{n}$  or  $\mathbf{b} \cdot \mathbf{n} = 0$ .

**Example 68.** Find the angle between the line  $\mathbf{r} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}} + \lambda(\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}})$  and the plane  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) = 4$ .

**Sol.** We know that if  $\theta$  is the angle between the lines  $\mathbf{r} = \mathbf{a} + \lambda \mathbf{b}$  and  $\mathbf{r} \cdot \mathbf{n} = p$ , then  $\sin \theta = \left| \frac{\mathbf{b} \cdot \mathbf{n}}{|\mathbf{b}| |\mathbf{n}|} \right|$ 

Therefore, if  $\theta$  is the angle between  $\mathbf{r} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}} + \lambda(\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}})$  and  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) = 4$ , then

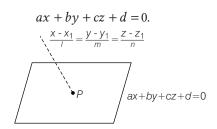

$$\sin \theta = \left| \frac{(\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) \cdot (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}})}{|\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}| |2\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}|} \right|$$

$$= \frac{2 + 1 + 1}{\sqrt{1 + 1 + 1} \sqrt{4 + 1 + 1}} = \frac{4}{\sqrt{3} \sqrt{6}} = \frac{4}{3\sqrt{2}}$$

$$\Rightarrow \theta = \sin^{-1} \left(\frac{4}{3\sqrt{2}}\right)$$

## Intersection of a Line and a Plane

To find the point of intersection of the line  $\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}$  and the plane

Let 
$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n} = r$$

$$\therefore \qquad (x = rl + x_1, y = mr + y_1, z = nr + z_1)$$

be a point in the plane say *P*.

It must satisfy the equation of plane.

$$a(x_1 + lr) + b(y_1 + mr) + c(z_1 + nr) + d = 0$$

$$\Rightarrow (ax_1 + by_1 + cz_1 + d) + r(al + bm + cn) = 0$$

$$\Rightarrow r = -\frac{(ax_1 + by_1 + cz_1 + d)}{al + bm + cn}$$

On substituting the value of r Eq. (i), we get the coordinates of the required point of intersection.

#### (i) Condition for a Line to be Parallel to a Plane

Let line 
$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}$$
 be parallel to plane  $ax + by + cz + d = 0$  iff;

$$\theta = 0$$
 or  $\pi$  or  $\sin \theta = 0 \implies al + bm + cm = 0$ 

#### (iii) Condition for a Line to Lie in the Plane

Condition for 
$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}$$
 to lie in the plane  $ax + by + cz + d = 0$  are

$$al + bm + cn = 0$$
 and  $ax_1 + by_1 + cz_1 + d = 0$ 

#### Note

A line will be in a plane iff

- (i) the normal to the plane is perpendicular to the line.
- (ii) a point on the line in the plane.

**Example 69.** Find the distance between the point with position vector  $-\mathbf{i} - 5\mathbf{j} - 10\mathbf{k}$  and the point of intersection of the line  $\frac{x-2}{3} = \frac{y+1}{4} = \frac{z-2}{12}$  with the plane x - y + z = 5.

**Sol.** The coordinates of any point on the line 
$$\frac{x-2}{3} = \frac{y+1}{4} = \frac{z-2}{2} = r \text{ (say) are } (3r+2, 4r-1, 12r+2)$$

If it lies on the plane x - y + z = 5, then

$$3r + 2 - 4r + 1 + 12r + 2 = 5 \Rightarrow 11r = 0 \Rightarrow r = 0.$$

Putting r = 0 in (i), we obtain (2, -1, 2) as the coordinates of the point of intersection of the given line and plane.

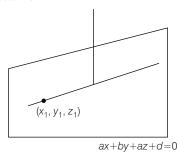

Required distance = distance between points (-1, -5, -10) and  $(2, -1, 2) = \sqrt{(2+1)^2 + (-1+5)^2 + (2+10)^2}$ 

$$=\sqrt{9+16+144}=\sqrt{169}=13$$

## **Coplanarity of Two Lines**

The straight line  $\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}$  lies in a given plane ax + by + cz + d = 0 if  $ax_1 + by_1 + cz_1 + d = 0$ 

and al + bm + cn = 0

Thus, the general equation of the plane containing a straight line

$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n} \text{ is}$$

$$a(x - x_1) + b(y - y_1) + c(z - z_1) = 0$$

$$al + bm + cn = 0$$

where,

The equation of the plane containing a straight line  $\frac{x-x_1}{l} = \frac{y-y_1}{m} = \frac{z-z_1}{n}$  and parallel to the straight line  $\frac{x - x_2}{l_1} = \frac{y - y_2}{m_1} = \frac{z - z_2}{n_1}$  is

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ l & m & n \\ l_1 & m_1 & n_1 \end{vmatrix} = 0$$

Hence, the equation of the plane containing two given straight lines

and 
$$\frac{x - x_1}{l} = \frac{y - y_1}{m} = \frac{z - z_1}{n}$$

$$\frac{x - x_2}{l_1} = \frac{y - y_2}{m_1} = \frac{z - z_2}{n_1}$$

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ l & m & n \\ l_1 & m_1 & n_1 \end{vmatrix} = 0$$

or

$$\begin{vmatrix} x - x_2 & y - y_2 & z - z_2 \\ l & m & n \\ l_1 & m_1 & n_1 \end{vmatrix} = 0$$

If the lines  $\mathbf{r} = \mathbf{a}_1 + \lambda \mathbf{b}_1$  and  $\mathbf{r} = \mathbf{a}_2 + \lambda \mathbf{b}_2$  are coplanar,

$$[\mathbf{a}_1 \ \mathbf{b}_1 \ \mathbf{b}_2] = [\mathbf{a}_2 \ \mathbf{b}_1 \ \mathbf{b}_2]$$

and the equation of plane containing them is

$$[\mathbf{r} \ \mathbf{b}_1 \ \mathbf{b}_2] = [\mathbf{a}_1 \ \mathbf{b}_1 \ \mathbf{b}_2]$$
$$[\mathbf{r} \ \mathbf{b}_1 \ \mathbf{b}_2] = [\mathbf{a}_2 \mathbf{b}_1 \ \mathbf{b}_2]$$

or

**Example 70.** Find the equation of plane passing through the point (0, 7, -7) and containing the line  $\frac{x+1}{-3} = \frac{y-3}{2} = \frac{z+2}{1}$ .

**Sol.** Let the equation of the plane passing through the point 
$$(0,7,-7)$$
 be  $a(x-0)+b(y-7)+c(z+7)=0$  ...(i)

The line 
$$\frac{x+1}{-3} = \frac{y-3}{2} = \frac{z+2}{1}$$
 passes through the point

(-1, 3, -2) and has direction ratios -3, 2, 1. If (i) contains this line, it must pass through (-1, 3, -2) and must be parallel to the line. Therefore,

$$a(-1) + b(3-7) + c(-2+7) = 0$$
 i.e. 
$$a(-1) + b(-4) + c(5) = 0$$
 ...(ii) and 
$$-3a + 2b + 1c = 0$$
 ...(iii)

On solving Eqs. (ii) and (iii) by cross multiplication, we get

$$\frac{a}{-14} = \frac{b}{-14} = \frac{c}{-14} \implies \frac{a}{1} = \frac{b}{1} = \frac{c}{1} = \lambda$$
 (say)

$$\rightarrow$$

$$a = \lambda$$
,  $b = \lambda$ ,  $c = \lambda$ 

Putting the values of a, b, c in (i), we obtain

$$\lambda(x-0) + \lambda(y-7) + \lambda(z+7) = 0$$

$$\Rightarrow$$

$$x + y + z = 0$$

This is the equation of the required plane.

**Example 71.** Prove that the lines  $\frac{x+1}{3} = \frac{y+3}{5} = \frac{z+5}{7}$ and  $\frac{x-2}{1} = \frac{y-4}{4} = \frac{z-6}{7}$  are coplanar. Also, find the

plane containing these two lines.

**Sol.** We know that, the line  $\frac{x-x_1}{l_1} = \frac{y-y_1}{m_1} = \frac{z-z_1}{n_1}$ 

and 
$$\frac{x-x_2}{l_2} = \frac{y-y_2}{m_2} = \frac{z-z_2}{n_2}$$
 are coplanar if

and 
$$\frac{x - x_2}{l_2} = \frac{y - y_2}{m_2} = \frac{z - z_2}{n_2}$$
 are coplanar if
$$\begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = 0$$

and the equation of the plane containing these two lines is

$$\begin{vmatrix} x - x_1 & y - y_1 & z - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = 0$$

$$m_1 = 5, n_1 = 7, l_2 = 1, m_2 = 4, n_2 = 7$$

$$\begin{vmatrix} x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ l_1 & m_1 & n_1 \\ l_2 & m_2 & n_2 \end{vmatrix} = \begin{vmatrix} 3 & 7 & 11 \\ 3 & 5 & 7 \\ 1 & 4 & 7 \end{vmatrix} = 0$$

so, the given lines are coplanar.

The equation of the plane containing the lines is

$$\begin{vmatrix} x+1 & y+3 & z+5 \\ 3 & 5 & 7 \\ 1 & 4 & 7 \end{vmatrix} = 0$$

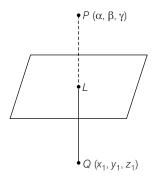

ar 
$$(x + 1)(35 - 28) - (y + 3)(21 - 7) + (z + 5)(12 - 5) = 0$$
  
or  $x - 2y + z = 0$ .

## Image of a Point in a Plane

To find the image of the point  $(\alpha, \beta, \gamma)$  in the plane

$$ax + by + cz + d = 0 \qquad \dots (i)$$

Let  $Q(x_1, y_1, z_1)$  be the image of point P in the plane (i).

Let PQ meet plane (i) at L, direction ratios of normal to plane (i) are (a, b, c), since PQ perpendicular of plane (i).

So, direction ratios of PQ are a, b, c.

 $\Rightarrow$  Equation of line PQ is,

$$\frac{x-\alpha}{a} = \frac{y-\beta}{b} = \frac{z-\gamma}{c} = r$$
 (say)

Coordinate of any point on line PQ may be taken as

$$(ar + \alpha, br + \beta, cr + \gamma)$$

Let

$$Q(ar + \alpha, br + \beta, cr + \gamma)$$

Since, *L* is the middle point of *PQ* 

$$L = \left(\alpha + \frac{ar}{2}, \beta + \frac{br}{2}, \gamma + \frac{cr}{2}\right)$$

Since, L lies on plane (i), we get

$$a\left(\frac{ar}{2} + \alpha\right) + b\left(\frac{br}{2} + \beta\right) + c\left(\frac{cr}{2} + \gamma\right) + d = 0$$

$$\Rightarrow (a^2 + b^2 + c^2) \frac{r}{2} = -(a\alpha + b\beta + c\gamma + d)$$

$$\Rightarrow r = \frac{-2(a\alpha + b\beta + c\gamma + d)}{a^2 + b^2 + c^2}$$

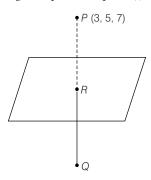

**Example 72.** Find the image of the point P(3, 5, 7) in the plane 2x + y + z = 0.

**Sol.** Given plane is 
$$2x + y + z = 0$$
 ...(i)

and the point P(3, 5, 7)

DR's of normal to the plane (i) are 2, 1, 1.

Let Q be the image of a point P in plane (i).

∴ Equation of line *PR* is  $\frac{x-3}{2} = \frac{y-5}{1} = \frac{z-7}{1} = r$ 

Let R(2r + 3, r + 5, r + 7)

Since, R lies on plane (i).

$$\therefore 2(2r+3) + (r+5) + (r+7) = 0; 6r+18 = 0$$

$$\therefore \qquad r = -3 \ \therefore \qquad R \equiv (-3, 2, 4)$$

Let  $Q \equiv (\alpha, \beta, \gamma)$ 

Since, *R* is mid-point of *PQ*.

$$\therefore \qquad -3 = \frac{\alpha + 3}{2} \implies \alpha = -9$$

$$2 = \frac{\beta + 5}{2} \implies \beta = -1$$

$$4 = \frac{\gamma + 7}{2} \implies \gamma = 1$$

$$\therefore \qquad Q \equiv (-9, 1, 1)$$

**Example 73.** Find the length and the foot of the perpendicular from the point (7, 14, 5) to the plane 2x + 4y - z = 2.

**Sol.** The required length = 
$$\frac{2(7) + 4(14) - (5) - 2}{\sqrt{2^2 + 4^2 + 1^2}}$$
$$= \frac{14 + 56 - 5 - 2}{\sqrt{4 + 16 + 1}} = \frac{63}{\sqrt{21}}$$

Let the coordinates of the foot of the perpendicular from the point P(7, 14, 5) be  $M(\alpha, \beta, \gamma)$ .

Then, the direction ratios of PM are  $\alpha - 7$ ,  $\beta - 14$  and  $\gamma - 5$ .

Therefore, the direction ratios of the normal to the plane are  $\alpha$  -7,  $\beta$  - 14 and  $\gamma$  -5.

But the direction ratios of normal to the given plane 2x + 4y - z = 2 are 2, 4 and -1.

Hence,  $\frac{\alpha - 7}{2} = \frac{\beta - 14}{4} = \frac{\gamma - 5}{-1} = k$ 

$$\alpha = 2k + 7, \beta = 4k + 14 \text{ and } \gamma = -k + 5$$
 ...(i)

Since,  $\alpha$ ,  $\beta$  and  $\gamma$  lie on the plane 2x + 4y - z = 2,  $2\alpha + 4\beta - \gamma = 2$ 

$$\Rightarrow$$
 2(7 + 2k) + 4(14 + 4k) - (5 - k) = 2

$$\Rightarrow$$
 14 + 4k + 56 + 16k - 5 + k = 2

$$\Rightarrow$$
  $21k = -63 \Rightarrow k = -3$ 

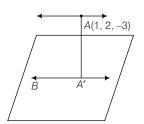

Now, putting k = -3 in (i), we get  $\alpha = 1, \beta = 2, \gamma = 8$ 

Hence, the foot of the perpendicular is (1, 2, 8).

**Example 74.** Find the image of the line  $\frac{x-1}{9} = \frac{y-2}{-1}$ 

$$=\frac{z+3}{-3}$$
 in the plane  $3x-3y+10z-26=0$ .

Sol.

$$\frac{x-1}{0} = \frac{y-2}{-1} = \frac{z+3}{-3}$$
 ...(i)

$$3x - 3y + 10z - 26 = 0$$
 ...(ii)

The direction ratios of the line are 9, -1 and -3 and direction ratios of the normal to the given plane are 3, -3 and 10.

Since,  $9 \cdot 3 + (-1)(-3) + (-3)10 = 0$  and the point (1, 2, -3) of line (i) does not lie in plane (ii) for

 $3 \cdot 1 - 3 \cdot 2 + 10 \cdot (-3) - 26 \neq 0$ , line (i) is parallel to plane (ii). Let A' be the image of point A(1, 2, -3) in plane (ii). Then the image of the line (i) in the plane (ii) is the line through A' and parallel to the line (i).

Let point A' be (p, q, r). Then

$$\frac{p-1}{3} = \frac{q-2}{-3} = \frac{r+3}{10}$$
$$= -\frac{(3(1)-3(2)+10(-3)-26)}{9+9+100} = \frac{1}{2}$$

The point  $A'\left(\frac{5}{2},\frac{1}{2},2\right)$ 

The equation of line BA' is 
$$\frac{x-\left(\frac{5}{2}\right)}{9} = \frac{y-\left(\frac{1}{2}\right)}{-1} = \frac{z-2}{-3}$$

# **Session 4**

# **Sphere**

## **Sphere**

A sphere is the locus of a point which moves in space in such a way that its distance from a fixed point always remains constant. The fixed point is called the centre of the sphere and the fixed distance is called the radius of sphere. Shown as in adjoining figure.

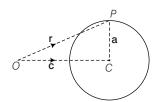

# Equation of Sphere whose Centre c and Radius is a

Let *O* be the origin of reference and **C** be the centre of sphere whose position vector is **c**. Let *P* be any point on the surface of the sphere whose position vector is **r**.

Thus, 
$$OP = r$$
 and  $OC = c$   

$$\therefore CP = OP - OC = r - c$$

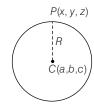

Now,  $|\mathbf{r} - \mathbf{c}| = \mathbf{a}$  [radius of sphere]  $\Rightarrow |\mathbf{r} - \mathbf{c}|^2 = \mathbf{a}^2$   $\Rightarrow (\mathbf{r} - \mathbf{c}) \cdot (\mathbf{r} - \mathbf{c}) = \mathbf{a}^2$   $\Rightarrow r^2 - 2\mathbf{r} \cdot \mathbf{c} + c^2 = \mathbf{a}^2$   $\Rightarrow r^2 - 2r \cdot \mathbf{c} + (c^2 - a^2) = 0$ 

which is the required equation of sphere.

## Cartesian Equation of a Sphere

The equation of sphere with centre (a, b, c) and radius R is

$$(x-a)^2 + (y-b)^2 + (z-c)^2 = R^2$$

**Proof.** Let *C* be the centre of the sphere.

Then, coordinates of C are (a, b, c). Let P(x, y, z) be any point on the sphere, then

$$CP = R$$

$$\Rightarrow CP^{2} = R^{2}$$

$$\Rightarrow (x-a)^{2} + (y-b)^{2} + (z-c)^{2} = R^{2}$$

Since, P(x, y, z) is an arbitrary point on the sphere, therefore required equation of the sphere is

$$(x-a)^2 + (y-b)^2 + (z-c)^2 = R^2$$

#### Remarks

1. The above equation is called the central form of a sphere. If the centre is at the origin, then equation of sphere is,

$$x^2 + y^2 + z^2 = R^2$$

(known as the standard form of the sphere)

2. Above equation can also be written as

$$x^{2} + y^{2} + z^{2} - 2ax - 2by - 2cz + (a^{2} + b^{2} + c^{2} - R^{2}) = 0$$

which has the following characteristics of the equation of sphere

- (i) It is a second degree equation in x, y and z.
- (ii) The coefficient of  $x^2$ ,  $y^2$  and  $z^2$  are all equal.
- (iii) The term containing the product of xy, yz and zx are absent.

**Example 75.** Find the vector equation of a sphere with centre having the position vector  $\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}$  and radius  $\sqrt{3}$ .

**Sol.** We know that equation of sphere is

$$|\mathbf{r} - \mathbf{c}| = a$$
 (vector form)  
$$\Rightarrow |\mathbf{r} - (\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}})| = \sqrt{3}$$

which is the required equation of sphere.

**Example 76.** Find the equation of sphere whose centre is (5, 2, 3) and radius is 2 in cartesian form.

**Sol.** The required equation of the sphere is

$$(x-5)^{2} + (y-2)^{2} + (z-3)^{2} = 2^{2}$$

$$\Rightarrow x^{2} + y^{2} + z^{3} - 10x - 4y - 6z + 34 = 0$$

**Example 77.** Find the equation of a sphere whose centre is (3, 1, 2) and radius is 5.

**Sol.** The equation of the sphere whose centre is (3, 1, 2) and radius is 5, is

$$(x-3)^{2} + (y-1)^{2} + (z-2)^{2} = 5^{2}$$
$$x^{2} + y^{2} + z^{2} - 6x - 2y - 4z - 11 = 0$$

### General Equation of Sphere

The equation  $x^2 + y^2 + z^2 + 2ux + 2vy + 2wz + d = 0$ represents a sphere with centre (-u, -v, -w) i.e.

$$\left(-\frac{1}{2} \text{ coefficient of } x, -\frac{1}{2} \text{ coefficient of } y, -\frac{1}{2} \text{ coefficient of } z\right)$$

and radius =  $\sqrt{u^2 + v^2 + w^2 - d}$ .

#### Note

The equation  $x^2 + y^2 + z^2 + 2ux + 2vy + 2wz + d = 0$  represents a real sphere, if  $u^2 + v^2 + w^2 - d > 0$ . If  $u^2 + v^2 + w^2 - d = 0$ , then it represents a point sphere. The sphere is imaginary, if  $u^2 + v^2 + w^2 - d < 0$ .

**Example 78.** Find the centre and radius of the sphere  $2x^2 + 2y^2 + 2z^2 - 2x - 4y + 2z + 3 = 0$ .

Sol. The given equation

$$x^{2} + y^{2} + z^{2} - x - 2y + z + \frac{3}{2} = 0;$$

where cetnre is

$$\left(-\frac{1}{2} \text{ coefficient of } x, -\frac{1}{2} \text{ coefficient of } y, -\frac{1}{2} \text{ coefficient of } z\right)$$

$$\therefore \qquad \text{Centre} = \left(\frac{1}{2}, -1, -\frac{1}{2}\right)$$

and

Radius = 
$$\sqrt{\left(\frac{1}{2}\right)^2 + (-1)^2 + \left(-\frac{1}{2}\right)^2 - \frac{3}{2}}$$
  
=  $\sqrt{\frac{1}{4} + 1 + \frac{1}{4} - \frac{3}{2}} = 0$ 

 $\therefore$  Given sphere represents a point sphere  $\left(\frac{1}{2}, -1, -\frac{1}{2}\right)$ .

**Example 79.** Find the equation of the sphere passing through (0, 0, 0), (1, 0, 0), (0, 1, 0) and (0, 0, 1).

**Sol.** Let the equation of the sphere be

$$x^{2} + y^{2} + z^{2} + 2ux + 2vy + 2wz + d = 0$$
 ...(i)

As (i) passes through (0, 0, 0), (1, 0, 0), (0, 1, 0) and (0, 0, 1), we must have d = 0, 1 + 2u + d = 0

$$1 + 2v + d = 0$$
 and  $1 + 2w + d = 0$ 

Since, d = 0, we get 2u = 2v = 2w = -1

Thus, the equation of the required sphere is

$$x^2 + y^2 + z^2 - x - y - z = 0.$$

**Example 80.** Find the equation of a sphere which passes through (1, 0, 0), (0, 1, 0) and (0, 0, 1) and has radius as small as possible.

**Sol.** Let the equation of the required sphere be

$$x^{2} + y^{2} + z^{2} + 2ux + 2vy + 2wz + d = 0$$
 ...(i)

As the sphere passes through (1, 0, 0), (0,1, 0) and (0, 0, 1), we get

$$1 + 2u + d = 0, 1 + 2v + d = 0$$
 and  $1 + 2w + d = 0$   
 $u = v = w = -\frac{1}{2}(d+1)$ 

If *R* is the radius of the sphere, then  $R^2 = u^2 + v^2 + w^2 - d$ 

$$\Rightarrow R^{2} = \frac{3}{4} (d+1)^{2} - d$$

$$= \frac{3}{4} \left[ d^{2} + 2d + 1 - \frac{4}{3} d \right]$$

$$= \frac{3}{4} \left[ d^{2} + \frac{2}{3} d + 1 \right]$$

$$= \frac{3}{4} \left[ \left( d + \frac{1}{3} \right)^{2} + 1 - \frac{1}{9} \right]$$

$$= \frac{3}{4} \left[ \left( d + \frac{1}{3} \right)^{2} + \frac{8}{9} \right]$$

The last equation shows that  $R^2$  (and thus R) will be the least if an only if  $d = -\frac{1}{2}$ .

Therefore, 
$$u = v = w = -\frac{1}{2}\left(1 - \frac{1}{3}\right) = -\frac{1}{3}$$

Hence, the equation of the required sphere is  $x^2 + y^2 + z^2 - \frac{2}{3}$ 

$$(x + y + z) - \frac{1}{3} = 0 \text{ or } 3(x^2 + y^2 + z^2) - 2(x + y + z) - 1 = 0.$$

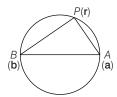

## Diameter Form of the Equation of a Sphere

If the position vectors of the extremities of a diameter of a sphere are **a** and **b**, then its equation is

$$(\mathbf{r} - \mathbf{a}) \cdot (\mathbf{r} - \mathbf{b}) = 0$$

$$\Rightarrow |\mathbf{r}|^2 - \mathbf{r} \cdot (\mathbf{a} + \mathbf{b}) + \mathbf{a} \cdot \mathbf{b} = 0$$

**Proof.** Let **a** and **b** be the position vectors of the extremities A and B of a diameter AB of sphere. Let **r** be the position vector of any point P on the sphere. Then,

$$AP = r - a$$
 and  $BP = r - b$ 

Since, the diameter of a sphere subtends a right at any point on the sphere, therefore

$$\Rightarrow \angle APB = \frac{\pi}{2}$$

$$\Rightarrow AP \cdot BP = 0$$

$$\Rightarrow (\mathbf{r} - \mathbf{a}) \cdot (\mathbf{r} - \mathbf{b}) = 0$$

$$\mathbf{r} \cdot \mathbf{r} - \mathbf{r} \cdot \mathbf{b} - \mathbf{r} \cdot \mathbf{a} + \mathbf{a} \cdot \mathbf{b} = 0$$

$$|\mathbf{r}|^2 - (\mathbf{a} + \mathbf{b}) \cdot \mathbf{r} + \mathbf{a} \cdot \mathbf{b} = 0$$

This is the required equation of sphere.

#### **Vector Form**

If the position vectors of the extremities of a diameter of a sphere are  $\mathbf{a}$  and  $\mathbf{b}$ , then its equation is

$$|\mathbf{r} - \mathbf{a}|^2 + |\mathbf{r} - \mathbf{b}|^2 = |\mathbf{a} - \mathbf{b}|^2$$

**Proof.** Let **a** and **b** be the position vectors of the extremities A and B of a diameter of a sphere. Let  $\mathbf{r}$  be the position vector of any point *P* on the sphere, then

$$AP = r - a$$
$$BP = r - b$$

and

Since,  $\triangle APB$  is a right angled triangle.

$$AP^{2} + BP^{2} = AB^{2}$$

$$\Rightarrow |\mathbf{AP}|^{2} + |\mathbf{BP}|^{2} = |\mathbf{AB}|^{2}$$

$$\Rightarrow |\mathbf{r} - \mathbf{a}|^{2} + |\mathbf{r} - \mathbf{b}|^{2} = |\mathbf{a} - \mathbf{b}|^{2}$$

This is the required equation of the sphere.

#### Cartesian Form

If  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  are the coordinates of the extremities of a diameter of a sphere, then its equation is,  $(x-x_1)(x-x_2)+(y-y_1)(y-y_2)+(z-z_1)(z-z_2)=0$ 

**Example 81.** Find the equation of the sphere described on the joint of points A and B having Position position vectors  $2\mathbf{i} + 6\mathbf{j} - 7\mathbf{k}$  and  $-2\mathbf{i} + 4\mathbf{j} - 3\mathbf{k}$ , respectively, as the diameter. Find the centre and the radius of the sphere.

**Sol.** If point *P* with position vector  $\mathbf{r} = x \hat{\mathbf{i}} + y \hat{\mathbf{j}} + z \hat{\mathbf{k}}$  is any point on the sphere, then  $\mathbf{AP} \cdot \mathbf{BP} = 0$ 

$$(x-2)(x+2) + (y-6)(y-4) + (z+7)(z+3) = 0$$
  
 $\Rightarrow (x^2-4) + (y^2-10y+24) + (z^2+10z+21) = 0$ 

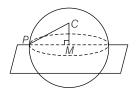

$$\Rightarrow x^2 + y^2 + z^2 - 10y + 10z + 41 = 0$$

The centre of this sphere is (0, 5, -5) and its radius is

$$\sqrt{5^2 + (-5)^2 - 41} = \sqrt{9} = 3$$

### Section of a Sphere by a Plane

Consider a sphere intersected by a plane. The set of points common to both sphere and plane is called a plane section of a sphere.

It can be easily seen the plane section of sphere is a circle.

Let *C* be the centre of the sphere and *M* be the foot of the perpendicular from C on the plane. Then, M is the centre of the circle and radius of circle is given by PM.

i.e. 
$$PM = \sqrt{CP^2 - CM^2}$$

The centre *M* of the circle is the point of intersection of the plane and line CM, which passes through C and is perpendicular to given plane.

**Example 82.** Find the radius of the circular section in which the sphere  $|\mathbf{r}| = 5$  is cut by the plane  $\mathbf{r} \cdot (\hat{\mathbf{i}} + \hat{\mathbf{i}} + \hat{\mathbf{k}}) = 3\sqrt{3}$ .

**Sol.** Let *A* be the foot of the perpendicular from the centre *O* to the plane  $\mathbf{r} \cdot (\mathbf{i} + \mathbf{j} + \mathbf{k}) - 3\sqrt{3} = 0$ 

Then, 
$$|OA| = \left| \frac{0 \cdot (\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}) - 3\sqrt{3}}{|\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}}|} \right| = \frac{3\sqrt{3}}{\sqrt{3}} = 3$$
 (perpendicular

distance of a point from the plane

If *P* is any point on the circle, then *P* lies on the plane as well as on the sphere. Therefore, OP = radius of the sphere = 5

Now, 
$$AP^2 = OP^2 - OA^2 = 5^2 - 3^2 = 16$$
  
 $\Rightarrow AP = 4$ 

### Example 83. Find the centre of the circle given by $\mathbf{r} \cdot (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) = 15$ and $|\mathbf{r} - (\hat{\mathbf{j}} + 2\hat{\mathbf{k}})| = 4$ .

**Sol.** The equation of a line through the centre  $\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$  and normal to the given plane is

$$\mathbf{r} = (\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) + \lambda(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) \qquad \dots(i)$$

This meets the plane at a point for which we must have

$$[(\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) + \lambda(\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}})] \cdot (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}) = 15$$

$$\Rightarrow \qquad 6 + 9\lambda = 15$$

$$\Rightarrow \qquad \qquad \lambda = 1$$

On putting  $\lambda = 1$  in Eq. (i), we obtain the position vectors of the centre as  $\hat{i} + 3\hat{j} + 4\hat{k}$ , Hence, the coordinates of the centre of the circle are (1, 3, 4).

## Condition of Tengency of a Plane to a Sphere

A plane touches a given sphere, if the perpendicular distance from the centre of the sphere to the planes is equal to the radius of the sphere.

#### **Vector Form**

The plane  $\mathbf{r} \cdot \mathbf{n} = d$  touches the sphere  $|\mathbf{r} - \mathbf{a}| = R$ ,

if 
$$\frac{|\mathbf{a} \cdot \mathbf{n} - d|}{|\mathbf{n}|} = R$$

#### Cartesian Form

The plane lx + my + nz = p touches the sphere  $x^2 + y^2 + z^2 + 2ux + 2vy + 2wz + d = 0$ , if  $(ul + vm + wn + p)^2 = (l^2 + m^2 + n^2)(u^2 + v^2 + w^2 - d)$ 

**Example 84.** Show that the plane 2x - 2y + z + 12 = 0 touches the sphere  $x^2 + y^2 + z^2 - 2z - 4y + 2z - 3 = 0$ .

**Sol.** The given plane will touch the given sphere if the perpendicular distance from the centre of the sphere to the plane is equal to the radius of the sphere. The centre of the given sphere  $x^2 + y^2 + z^2 - 2x - 4y + 2z - 3 = 0$  is (1, 2, -1) and its radius is  $\sqrt{1^2 + 2^2 + (-1)^2 - (-3)} = 3$ .

Length of the perpendicular from (1, 2, -1) to the plane 2x-2y+z+12=0 is

$$\left| \frac{2(1) - 2(2) + (-1) + 12}{\sqrt{2^2 + (-2)^2 + 1^2}} \right| = \frac{9}{3} = 3$$

Thus, the given plane touches the given sphere.

**Example 85.** Find the equation of the sphere whose centre has the position vector  $3\hat{i} + 6\hat{j} - 4\hat{k}$  and which touches the plane  $\mathbf{r} \cdot (2\hat{i} - 2\hat{j} - \hat{k}) = 10$ .

**Sol.** Let the radius of the required sphere be *R*. Then, its equation is

$$|\mathbf{r} - (3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 4\hat{\mathbf{k}})| = R \qquad \dots (i)$$

Since, the plane  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - \hat{\mathbf{k}}) = 10$  touches the sphere (i), therefore length of perpendicular from the centre to the plane  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} - \hat{\mathbf{k}}) = 10$  is equal to R.

i.e. 
$$\frac{\left| \, (3\,\hat{\mathbf{i}} - 6\,\hat{\mathbf{j}} - 4\,\hat{\mathbf{k}}) \cdot (2\,\hat{\mathbf{i}} - 2\,\hat{\mathbf{j}} - \hat{\mathbf{k}}) - 10 \, \right|}{\left| \, 2\,\hat{\mathbf{i}} - 2\,\hat{\mathbf{j}} - \hat{\mathbf{k}} \, \right|} = R \ \, \Rightarrow \ \, R = 4$$

On putting R = 4 in Eq. (i), we obtain  $|\mathbf{r} - (3\hat{\mathbf{i}} + 6\hat{\mathbf{j}} - 4\hat{\mathbf{k}})| = 4$  as the equation of the required sphere.

**Example 86.** A variable plane passes through a fixed point (a,b,c) and cuts the coordinate axes at points A, B and C. Show that the locus of the centre of the sphere OABC is  $\frac{a}{x} + \frac{b}{y} + \frac{c}{z} = 2$ .

**Sol.** Let  $(\alpha, \beta, \gamma)$  be any point on the locus. Then according to the given condition,  $(\alpha, \beta, \gamma)$  is the centre of the sphere through the origin. Therefore, its equation is given by

$$(x - \alpha)^2 + (y - \beta)^2 + (z - \gamma)^2 = (0 - \alpha)^2 + (0 - \beta)^2 + (0 - \gamma)^2$$
  
$$x^2 + y^2 + z^2 - 2\alpha x - 2\beta y - 2\gamma z = 0$$

To obtain its point of intersection with the *X*-axis, we put v = 0 and z = 0, so that

$$x^2 - 2\alpha x = 0$$

$$\Rightarrow x(x - 2\alpha) = 0$$

$$\Rightarrow x = 0 \text{ or } x = 2\alpha$$
Thus the plane meets *Y*-axis at  $O(0, 0, 0)$  and  $A(2\alpha)$ 

Thus, the plane meets X-axis at O(0, 0, 0) and  $A(2\alpha, 0, 0)$ . Similarly, it meets Y-axis at O(0, 0, 0) and  $B(0, 2\beta, 0)$ , and Z-axis at O(0, 0, 0) and  $C(0, 0, 2\gamma)$ .

The equation of the plane through A, B and C is

$$\frac{x}{2\alpha} + \frac{y}{2\beta} + \frac{z}{2\gamma} = 1$$
 (intercept form)

Since, it passes through (a, b, c), we get

$$\frac{a}{2\alpha} + \frac{b}{2\beta} + \frac{c}{2\gamma} = 1$$
$$\frac{a}{\alpha} + \frac{b}{\beta} + \frac{c}{\gamma} = 2$$

Hence, locus of  $(\alpha, \beta, \gamma)$  is  $\frac{a}{x} + \frac{b}{y} + \frac{c}{z} = 2$ .

**Example 87.** A sphere of constant radius k passes through the origin and meets the axis at A, B and C. Prove that the centroid of triangle ABC lies on the sphere  $9(x^2 + y^2 + z^2) = 4k^2$ .

**Sol.** Let the equation of any sphere passing through the origin and having radius k be

$$x^2 + y^2 + z^2 + 2ux + 2vy + 2wz = 0$$

As the radius of the sphere is k, we get

$$u^2 + v^2 + w^2 = k^2$$

Note that (i) meets the *X*-axis at O(0, 0, 0) and A(-2u, 0, 0); *Y*-axis at O(0, 0, 0) and B(0, -2v, 0), and *Z*-axis at O(0, 0, 0) and C(0, 0, -2w).

Let the centroid of the triangle ABC be  $(\alpha, \beta, \gamma)$ . Then

$$\alpha = -\frac{2u}{3}, \beta = -\frac{2v}{3}, \gamma = -\frac{2w}{3}$$

$$\alpha = -\frac{3\alpha}{2}, v = -\frac{3\beta}{2}, w = -\frac{3v}{2}$$

Putting this in (ii), we get

$$\left(\frac{-3}{2}\alpha\right)^2 + \left(\frac{-3}{2}\beta\right)^2 + \left(\frac{-3}{2}\gamma\right)^2 = k^2$$
$$\alpha^2 + \beta^2 + \gamma^2 = \frac{4}{9}k^2$$

This shows that the centroid of triangle ABC lies on

$$x^2 + y^2 + z^2 = \frac{4}{9}k^2$$
.

$$\mathbf{r} \cdot (\hat{\mathbf{i}} + 9\hat{\mathbf{j}} + 11\hat{\mathbf{k}}) = 0$$

• Ex. 28 The vector equation of the plane through the point  $\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$  and perpendicular to the line of intersection of the plane  $\mathbf{r} \cdot (3\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) = 1$  and  $\mathbf{r} \cdot (\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 2\hat{\mathbf{k}}) = 2$ , is

(a) 
$$\mathbf{r} \cdot (2\hat{\mathbf{i}} + 7\hat{\mathbf{j}} - 13\hat{\mathbf{k}}) = 1$$
 (b)  $\mathbf{r} \cdot (2\hat{\mathbf{i}} - 7\hat{\mathbf{j}} - 13\hat{\mathbf{k}}) = 1$ 

(c) 
$$\mathbf{r} \cdot (2\hat{\mathbf{i}} + 7\hat{\mathbf{j}} + 13\hat{\mathbf{k}}) = 0$$
 (d) None of these

**Sol.** (b) The line of intersection of the planes

$$\mathbf{r} \cdot (3\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}) = 1$$

and

$$\mathbf{r} \cdot (\hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 2\hat{\mathbf{k}}) = 2$$

is common to both the planes. Therefore, it is perpendicular to normals to the two planes, i.e.

$$\mathbf{n}_1 = 3\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}}$$

and

$$\mathbf{n}_2 = \hat{\mathbf{i}} + 4\hat{\mathbf{j}} - 2\hat{\mathbf{k}}$$

Hence, it is parallel to the vector  $\mathbf{n}_1 \times \mathbf{n}_2 = -2\hat{\mathbf{i}} + 7\hat{\mathbf{j}} + 13\hat{\mathbf{k}}$ .

Thus, we have to find the equation of the plane passing through  $\mathbf{a} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}$  and normal to the vector  $\mathbf{n} = \mathbf{n}_1 \times \mathbf{n}_2$ .

The equation of the required plane is

$$(\mathbf{r} - \mathbf{a}) \cdot \mathbf{n} = 0$$

$$\Rightarrow \qquad \mathbf{r} \cdot \mathbf{n} = \mathbf{a} \cdot \mathbf{n}$$

$$\Rightarrow \qquad \mathbf{r} \cdot (-2\hat{\mathbf{i}} + 7\hat{\mathbf{j}} + 13\hat{\mathbf{k}}) = (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}) \cdot (-2\hat{\mathbf{i}} + 7\hat{\mathbf{j}} + 13\hat{\mathbf{k}})$$

$$\Rightarrow \qquad \mathbf{r} \cdot (2\hat{\mathbf{i}} - 7\hat{\mathbf{j}} - 13\hat{\mathbf{k}}) = 1$$

• Ex. 29 The cartesian equation of the plane

$$\mathbf{r} = (1 + \lambda - \mu)\hat{\mathbf{i}} + (2 - \lambda)\hat{\mathbf{j}} + (3 - 2\lambda + 2\mu)\hat{\mathbf{k}}, is$$

(a) 
$$2x + y = 5$$

(b) 
$$2x - y = 5$$

(c) 
$$2x + z = 5$$

(d) 
$$2x - z = 5$$

Sol. (c) We have,

$$\mathbf{r} = (1 + \lambda - \mu)\hat{\mathbf{i}} + (2 - \lambda)\hat{\mathbf{j}} + (3 - 2\lambda + 2\mu)\hat{\mathbf{k}}$$
  
$$\mathbf{r} = (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}) + \lambda(\hat{\mathbf{i}} - \hat{\mathbf{j}} - 2\hat{\mathbf{k}}) + \mu(-\hat{\mathbf{i}} + 2\hat{\mathbf{k}})$$

$$\Rightarrow \mathbf{r} = (\mathbf{1} + 2\mathbf{j} + 3\mathbf{k}) + \lambda(\mathbf{1} - \mathbf{j} - 2\mathbf{k}) + \mu(-1 + 2\mathbf{k})$$
which is a plane passing through  $\mathbf{a} = \hat{\mathbf{i}} + 2\hat{\mathbf{i}} + 3\hat{\mathbf{k}}$  and parall

which is a plane passing through  $\mathbf{a} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  and parallel to the vectors  $\mathbf{b} = \hat{\mathbf{i}} - \hat{\mathbf{j}} - 2\hat{\mathbf{k}}$  and  $\mathbf{c} = -\hat{\mathbf{i}} + 2\hat{\mathbf{k}}$ .

Therefore, it is normal to the vector

$$\mathbf{n} = \mathbf{b} \times \mathbf{c} = -2\hat{\mathbf{i}} - \hat{\mathbf{k}}$$

Hence, its vector equation is

$$(\mathbf{r} - \mathbf{a}) \cdot \mathbf{n} = 0$$

$$\Rightarrow$$
  $\mathbf{r} \cdot \mathbf{n} = \mathbf{a} \cdot \mathbf{n}$ 

$$\Rightarrow \qquad \mathbf{r} \cdot (-2\hat{\mathbf{i}} - \hat{\mathbf{k}}) = -2 - 3$$

$$\Rightarrow$$
  $\mathbf{r} \cdot (2\hat{\mathbf{i}} + \hat{\mathbf{k}}) = 5$ 

So, the cartesian equation of the plane is

$$(x \hat{\mathbf{i}} + y \hat{\mathbf{j}} + z \hat{\mathbf{k}}) \cdot (2 \hat{\mathbf{i}} + \hat{\mathbf{k}}) = 5 \Rightarrow 2x + z = 5$$

• Ex. 30 A variable plane is at a distance, k from the origin and meets the coordinates axis in A, B, C. Then, the locus of the centroid of  $\triangle ABC$  is

(a) 
$$x^{-2} + v^{-2} + z^{-2} = k^{-2}$$

(b) 
$$x^{-2} + y^{-2} + z^{-2} = 4k^{-2}$$

(c) 
$$x^{-2} + y^{-2} + z^{-2} = 16k^{-2}$$

(d) 
$$x^{-2} + v^{-2} + z^{-2} = 9k^{-2}$$

**Sol.** (d) Let the equation of the variable plane be  $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ .

This meets the coordinates axes at A(a, 0, 0), B(0, b, 0) and C(0, 0, c).

Let  $(\alpha, \beta, \gamma)$  be the coordinates of the centroid of  $\triangle ABC$ . Then,

$$\alpha = \frac{a}{3}, \beta = \frac{b}{3}, \gamma = \frac{c}{3}$$

$$a = 3\alpha, b = 3\beta, c = 3\gamma \qquad \dots(i)$$

The plane is at a distance, k from the origin.

$$\frac{\left|\frac{0}{a} + \frac{0}{b} + \frac{0}{c} - 1\right|}{\sqrt{\frac{1}{a^2} + \frac{1}{b^2} + \frac{1}{c^2}}} = k$$

$$\Rightarrow \frac{1}{a^2} + \frac{1}{b^2} + \frac{1}{c^2} = \frac{1}{k^2}$$

$$\Rightarrow \alpha^{-2} + \beta^{-2} + \gamma^{-2} = 9k^{-2}$$

Hence, the locus of  $(\alpha, \beta, \gamma)$  is  $x^{-2} + y^{-2} + z^{-2} = 9k^{-2}$

$$\Rightarrow (2+3\lambda)x + (\lambda-1)y + (\lambda+1)z - (3+5\lambda) = 0$$

So, 
$$\frac{1}{\sqrt{6}} = \frac{2(2+3\lambda) + (\lambda-1) - (\lambda+1) - 3 - 5\lambda}{\sqrt{(2+3\lambda)^2 + (\lambda-1)^2 + (\lambda+1)^2}}$$

 (b)  $b = 2c$ 

(c) 
$$a + b + c = 12$$
 (d)  $a + 2b + 2c = 0$ 

**Sol.** (a,b,c) Equation of any plane passing through

$$3A + 3B - C = 0$$
 and  $3A + B + 0 = 0$ 

$$\Rightarrow \frac{A}{1} = \frac{B}{-3} = \frac{C}{-6}.$$

So, the equation of the plane is

$$(x+2) - 3(y+2) - 6(z-2) = 0$$

or 
$$x - 3y - 6z + 8 = 0$$

or 
$$\frac{x}{-8} + \frac{y}{\frac{8}{3}} + \frac{z}{\frac{8}{6}} = 1 \implies a = 8, b = \frac{8}{3}, c = \frac{8}{6}$$

#### Passage I

(Ex. Nos. 46 to 48)

Two line whose equation are  $\frac{x-3}{2} = \frac{y-2}{3} = \frac{z-1}{\lambda}$  and

$$\frac{x-2}{3} = \frac{y-3}{2} = \frac{z-2}{3}$$

- Ex. 47 Point of intersection of the lines lies on
  - (a) 3x + y + z = 20
- (b) 2x + y + z = 25
- (c) 3x + 2v + z = 24

(b) 
$$\frac{\pi}{2}$$

(c) 
$$\frac{\pi}{6}$$

(d) 
$$\cos^{-1} \frac{2}{\sqrt{186}}$$

**Sol.** (Ex. 46-48)

**46.** (d) Both lines and coplanar

$$\begin{vmatrix} 2 & 3 & \lambda \\ 3 & 2 & 3 \\ 1 & -1 & -1 \end{vmatrix} = 0$$

$$\Rightarrow 2(-2+3)+3(3+3)+\lambda(-3-2)=0$$

$$\Rightarrow \qquad \qquad \lambda = 0$$

$$\sin^{-1}\sin 4 = \sin^{-1}\sin (\pi - 4) = \pi - 4$$

**47.** (d) Let 
$$\frac{x-3}{2} = \frac{y-2}{3} = \frac{z-1}{4} = r_1$$
  
 $\Rightarrow \qquad x = 3 + 2r_1$ 

$$y = 2 + 3r_1$$

$$z = 1 + 4r_1$$
It will lie on 
$$\frac{x-2}{3} = \frac{y-3}{2} = \frac{z-2}{3} \implies r_1 = 1$$

So, point of intersection is (5, 5, 5).

48. (b) Equation of plane contains both lines

$$\begin{vmatrix} x-3 & y-2 & z-1 \\ 2 & 3 & 4 \\ 3 & 2 & 3 \end{vmatrix} = 0$$

$$(x-3)(1) + (y-2)(12-6) + (z-1)(4-9) = 0$$
  
$$x + 6y - 5z = 10$$

Thus, the angle is  $\frac{\pi}{2}$ .

- $\therefore P$  lies in obtuse angle.
- **50.** (c)  $1 \times 2 + 2 \times 1 3 \times 3 < 0$

**54.** (a) The plane containing line AC and at a maximum distance from *B* must be perpendicular to the plane *OABC*.

The line of greatest slope on an inclined plane  $P_1$  is the line in the plane  $P_1$  which is perpendicular to the line of intersection of the plane  $P_1$  and a horizontal plane  $P_2$ .

• **Ex. 58** Assuming the plane 4x - 3y + 7z = 0 to be horizontal, the direction cosines of the line of greatest slope in the plane 2x + y - 5z = 0 are

(a) 
$$\frac{3}{\sqrt{11}}$$
,  $\frac{-1}{\sqrt{11}}$ ,  $\frac{1}{\sqrt{1}}$ 

(b) 
$$\frac{3}{\sqrt{11}}$$
,  $\frac{1}{\sqrt{11}}$ ,  $\frac{-1}{\sqrt{11}}$

(d) None of these

• Ex. 59 The equation of a line of greatest slope can be

 (b)  $\frac{x}{3} = \frac{y}{-1} = \frac{z}{1}$ 

(b) 
$$\frac{x}{3} = \frac{y}{-1} = \frac{z}{1}$$

$$(a)(6, 2, -2)$$

(b) 
$$(3, 1, -1)$$

(c) 
$$(6, -2, 2)$$

$$(d)(1,3,-1)$$

**Sol.** (Ex. 58-60)

**58.** (a) Plane  $P_1$  is of the form  $\mathbf{r} \cdot \mathbf{n}_1 = 0$ , where  $\mathbf{n}_1 = (4, -3, 7)$ 

Plane  $P_2$  is of the form  $\mathbf{r} \cdot \mathbf{n}_2 = 0$ ,

$$\mathbf{n}_2 = (2, 1, -5)$$

The vector  $\mathbf{b}$  along the line of intersection of planes is

$$\mathbf{n}_1 \times \mathbf{n}_1 = (4, 17, 5) = \mathbf{n}_3$$

Since the line of greatest slope is perpendicular to  $\mathbf{n}_3$  and  $\mathbf{n}_2$ the vector along the line of greatest slope

$$= \mathbf{n}_2 \times \mathbf{n}_3 = (3, -1, 1) = \mathbf{n}_4$$

**59.** (b) Since, (0, 0, 0) is a point on both planes, it lies on the line of intersection.

Hence, the equation a line of greatest slope can be

$$\frac{x}{3} = \frac{y}{-1} = \frac{z}{1}$$

**60.** (c) The point on the line  $\frac{x}{3} = \frac{y}{-1} = \frac{z}{1}$  at a distance  $2\sqrt{11}$  unit

$$\frac{x}{\frac{3}{\sqrt{11}}} = \frac{y}{\frac{-1}{\sqrt{11}}} = \frac{z}{1} = 2\sqrt{11}$$

The point is (6, -2, 2).

Column II

**Sol.** (A) 
$$\rightarrow$$
 (s), (B)  $\rightarrow$  (p), (C)  $\rightarrow$  (q), (D)  $\rightarrow$  (r)

(A) Both the lines pass through the point (7, 11, 15).

(B) < 2, 3, 4 > are direction ratios of both the lines. Also, the point (1, 2, 3) is common to both.

∴The lines are coincident.

(c) < 5, 4, -2 > are direction ratios of both the lines.

∴The lines are parallel.

Also, 
$$x = 2 + 5\lambda$$
,  $y = -3 + 4\lambda$ ,  $z = 5 - 2\lambda$   

$$\therefore \frac{2 + 5\lambda - 7}{5} = \frac{-3 + 4\lambda - 1}{4} = \frac{5 - 2\lambda - 2}{-2}$$
i.e.  $\lambda - 1 = \lambda - 1 = \frac{3 - 2\lambda}{2}$ 

∴No value of  $\lambda$ .

Thus, the lines are parallel and different.

(D) < 2, 3, 5 > and < 3, 2, 5 > are direction ratios of first and second line, respectively.

C. A line passes through two points 
$$A(2, -3, -1)$$

D. The coordinates of the foot of the perpendicular s. (14,1,5) from the point (3, -1,11) on the line

(A) The given line is x = 4y + 5, z = 3y - 6,

or 
$$\frac{x-5}{4} = y$$
,  $\frac{z+6}{3} = y$   
or  $\frac{x-5}{4} = \frac{y}{1} = \frac{z+6}{3} = \lambda$  (say)

Any point on the line is of the form  $(4\lambda + 5, \lambda, 3\lambda - 6)$ .

The distance between  $(4\lambda + 5, \lambda, 3\lambda - 6)$  and (5, 3, -6) is 3 units

Therefore, 
$$(4\lambda + 5 - 5)^2 + (\lambda - 3)^2 + (3\lambda - 6 + 6)^2 = 9$$
  

$$\Rightarrow 16\lambda^2 + \lambda^2 + 9 - 6\lambda + 9\lambda^2 = 9$$

$$\Rightarrow 26\lambda^2 - 6\lambda = 0$$

$$\Rightarrow \qquad \qquad \lambda = 0, \frac{3}{13}$$

The point is (5, 0, -6)

(B) The equation of the plane containing the lines

$$\frac{x-2}{3} = \frac{y+3}{5} = \frac{z+5}{7}$$
 and parallel to  $\hat{\mathbf{i}} + 4\hat{\mathbf{j}} + 7\hat{\mathbf{k}}$ .

$$\begin{vmatrix} x-2 & y+3 & z+5 \\ 1 & 4 & 7 \\ 3 & 5 & 7 \end{vmatrix} = 0 \implies x-2y+z-3=0$$

Point (-1, -2, 0) lies on this plane.

(C) The line passing through points A(2, -3, -1)

and 
$$B(8, -1, 2) \text{ is } \frac{x-2}{8-2} = \frac{y+3}{-1+3} = \frac{z+1}{2+1}$$
or 
$$\frac{x-2}{6} = \frac{y+3}{2} = \frac{z+1}{3} = \lambda$$
 (say)

Any point on this line is of the form  $P(6\lambda + 2, 2\lambda - 3, 3\lambda - 1)$ , whose distance from point A(2, -3, -1) is 14 units. Therefore,

$$\Rightarrow$$
  $PA = 14 \Rightarrow PA^2 = (14)^2$ 

$$\Rightarrow \qquad (6\lambda)^2 + (2\lambda)^2 + (3\lambda)^2 = 196$$

$$\Rightarrow$$
  $49\lambda^2 = 196 \Rightarrow \lambda^2 = 4 \Rightarrow \lambda = \pm 2$ 

Therefore, the required points are (14, 1, 5) and (-10, -7, -7). The point nearer to the origin is (14, 1, 5).

(D) Any point on line AB, 
$$\frac{x}{2} = \frac{y-2}{3} = \frac{z-3}{4} = \lambda$$
 is

 $M(2\lambda, 3\lambda + 2, 4\lambda + 3)$ . Therefore, the direction ratios of PM are  $2\lambda - 3$ ,  $3\lambda + 3$  and  $4\lambda - 8$ .

But  $PM \perp AB$ 

$$2(2\lambda - 3) + 3(3\lambda + 3) + 4(4\lambda - 8) = 0$$

$$4\lambda - 6 + 9\lambda + 9 + 16\lambda - 32 = 0$$

$$29\lambda - 29 = 0 : \lambda = 1$$

Therefore, foot of the perpendicular is M(2, 5, 7).

(A) If the required image is (x, y, z), then

$$\frac{x-3}{2} = \frac{y-5}{1} = \frac{z-7}{1} = -\frac{2(6+5+7+18)}{2^2+1^2+1^2}$$
$$= -12 \text{ or } (-21, -7, -5).$$

(B) Any point on the line 
$$\frac{x-2}{-3} = \frac{y-1}{2} = \frac{z-3}{2} = \lambda$$
 is

 $(-3\lambda +2, 2\lambda +1, 2\lambda +3)$ , which lies on plane 2x + y - z = 3. Therefore,

$$-6\lambda + 4 + 2\lambda + 1 - 2\lambda - 3 = 3$$
$$-6\lambda = 1$$
$$\lambda = -\frac{1}{6}$$

Therefore, the point is 
$$\left(\frac{5}{2}, \frac{2}{3}, \frac{8}{3}\right)$$

(C) If (x, y, z) is required foot of the perpendicular, then

$$\frac{x-1}{2} = \frac{y-1}{-2} = \frac{z-2}{4} = \frac{(2-2+8+5)}{2^2 + (-2)^2 + 4^2}$$

or 
$$(x, y, z) \equiv \left(\frac{-1}{12}, \frac{25}{12}, \frac{-2}{12}\right)$$

(D) Any point on the line  $\frac{x-1}{2} = \frac{y-2}{3} = \frac{z-3}{4} = \lambda$  is

 $P(2\lambda + 1, 3\lambda + 2, 4\lambda + 3)$ , which satisfies the line

$$\frac{x-4}{5} = \frac{y-1}{2} = \frac{z}{1}$$
or
$$\frac{2\lambda + 1 - 4}{5} = \frac{3\lambda + 2 - 1}{2} = \frac{4\lambda + 3}{1}$$

The required point is (-1, -1, -1).

## • Ex. 65 $\frac{x-2}{3} = \frac{y-3}{4} = \frac{z-4}{5}$

**Sol.** (A) 
$$\rightarrow$$
 (r, s), (B)  $\rightarrow$  (p), (C)  $\rightarrow$  (q), (D)  $\rightarrow$  (s)

D. Point on the line common to the plane

x + y - z + 3 = 0

 $\Rightarrow$ 

Any point on the line is (3r+2, 4r+3, 5r+4)

(A) 
$$(3r + 2 - 2)^2 + (4r + 3 - 3)^2 + (5r + 4 - 4)^2 = 200$$

$$\Rightarrow$$
  $(9+16+25)r^2=200 \Rightarrow r=\pm 2$ 

For r = 2, the point is (8, 11, 14), For r = -2 it is (-4, -5, -6)

(B) 
$$3r + 2 + 4r + 3 + 5r + 4 + 3 = 0$$

$$12r + 12 = 0 \Longrightarrow r = -1$$

and the point on the line common to the plane is (-1, -1, -1).

(C) 
$$(3r + 2)^2 + (4r + 3)^2 + (5r + 4)^2 = 29$$

$$50r^2 + 76r = 0 \implies r = 0, r = -\frac{76}{50}$$

For r = 0, the point is (2, 3, 4).

(D) 
$$3r + 2 + 4r + 3 - 5r - 4 + 3 = 0$$

$$2r + 4 = 0 \implies r = -2$$

 $\therefore$  The point on the line common to the plane is (-4, -5, -6)

Equation of planes passing through the line of intersection of planes (i) and (ii) may be taken as

### Subjective Type Questions

• Ex. 71 The equation of motion of rockets are

$$x = 2t$$
,  $y = -4t$ ,  $z = 4t$ ,

where the time 't' is given in second and the coordinates of a moving point in kilometres.

What is the path of the rocket? At what distance will the rocket be from the starting point O(0,0,0) in 10s.

**Sol.** Eliminating 't' from the given equations, we get the equation of the path,

$$\frac{x}{2} = \frac{y}{-4} = \frac{z}{4}$$

or 
$$\frac{x}{1} = \frac{y}{-2} = \frac{z}{2}$$

Thus, the path of the rocket represents a straight line passing through the origin.

For 
$$t = 10 \text{ s}$$

We have, 
$$x = 20$$
,  $y = -40$ ,  $z = 40$ 

and 
$$|\mathbf{r}| = |\mathbf{OM}| = \sqrt{x^2 + y^2 + z^2}$$
  
=  $\sqrt{400 + 1600 + 1600} = 60 \text{ km}$ 

**Ex. 72** Write the equation of a tangent to the curve x = t,  $y = t^2$ ,  $z = t^3$  at its point M(1, 1, 1); (t = 1).

**Sol.** Here, 
$$\mathbf{r} = t\hat{\mathbf{i}} + t^2\hat{\mathbf{j}} + t^3\hat{\mathbf{k}}$$

$$\frac{dr}{dt} = \hat{\mathbf{i}} + 2t\hat{\mathbf{j}} + 3t^2\hat{\mathbf{k}}$$

Hence, the direction of the tangent at the point *M* is determined by the vector.

$$\left(\frac{dr}{dt}\right)_{M} = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$$

Thus, the equation of the desired tangent is,

$$\frac{x-1}{1} = \frac{y-1}{2} = \frac{z-1}{3}$$

• Ex. 73 Find the locus of a point, the sum of squares of whose distances from the planes x - z = 0, x - 2y + z = 0 and x + y + z = 0 is 36.

**Sol.** Given planes are x - z = 0, x - 2y + z = 0

and 
$$x + y + z = 0$$
.

Let the point whose locus is required be  $P(\alpha, \beta, \gamma)$ . According

$$\begin{split} \frac{|\alpha + \gamma|^2}{2} + \frac{|\alpha - 2\beta + \gamma|^2}{6} + \frac{|\alpha + \beta + \gamma|^2}{3} &= 36\\ \text{or } 3(\alpha^2 + \gamma^2 - 2\alpha\gamma) + \alpha^2 + 4\beta^2 + \gamma^2 - 4\alpha\beta - 4\beta\gamma + 2\alpha\gamma \\ &+ 2(\alpha^2 + \beta^2 + \gamma^2 + 2\alpha\beta + 2\beta\gamma + 2\alpha\gamma) = 36 \times 6 \end{split}$$

or 
$$6\alpha^2 + 6\beta^2 + 6\gamma^2 = 36 \times 6$$
or 
$$\alpha^2 + \beta^2 + \gamma^2 = 36$$

Hence, the required equation of locus is

$$x^2 + y^2 + z^2 = 36$$

**Ex. 74** The plane ax + by = 0 is rotated through an angle  $\alpha$  about its line of intersection with the plane z = 0. Show that the equation to the plane in new position is  $ax + by \pm z\sqrt{a^2 + b^2} \tan \alpha = 0$ 

Sol. Given planes are

$$z = 0$$
 ...(1)  
$$z = 0$$
 ...(ii)

∴Equation of any plane passing through the line of intersection of planes (i) and (ii) may be taken as,

$$ax + by + kz = 0$$

The direction cosines of a normal to the plane (iii) are

$$\frac{a}{\sqrt{a^2 + b^2 + k^2}}, \frac{b}{\sqrt{a^2 + b^2 + k^2}}, \frac{k}{\sqrt{a^2 + b^2 + k^2}}$$

The direction cosines of a normal to the plane (i) are

$$\frac{a}{\sqrt{a^2+b^2}}, \frac{b}{\sqrt{a^2+b^2}}, 0$$

Since, the angle between the planes (i) and (iii) is  $\alpha$ .

$$\therefore \cos \alpha = \frac{a \cdot a + b \cdot b + k \cdot 0}{\sqrt{a^2 + b^2 + k^2}} \sqrt{a^2 + b^2}$$
$$= \sqrt{\frac{a^2 + b^2}{a^2 + b^2 + k^2}}$$

$$k^2 \cos^2 \alpha = \alpha^2 (1 - \cos^2 \alpha) + b^2 (1 - \cos^2 \alpha)$$

$$k^2 = \frac{(a^2 + b^2)\sin^2\alpha}{\cos^2\alpha}$$

On putting in Eq. (iii)  $k = \pm \sqrt{a^2 + b^2} \tan \alpha$ , we get equation of plane as.

$$ax + by \pm z\sqrt{a^2 + b^2} \tan \alpha = 0.$$

• **Ex. 75** Assuming the plane 4x - 3y + 7z = 0 to be horizontal, find the equation of the line of greatest slope through the point (2, 1, 1) in the plane 2x + y - 5z = 0.

**Sol.** The required line passing through the point (2, 1, 1) in the plane 2x + y - 5z = 0 and is having greatest slope, so it must be perpendicular to the line of intersection of the planes

$$2x + y - 5z = 0$$
 ...(i)

$$4x - 3y + 7z = 0 \qquad ...(ii)$$

Let the DR's of the line of intersection of Eqs. (i) and (ii) are *a*, b, c.

$$2a + b - 5c = 0$$

and

$$4a - 3b + 7c = 0$$

(as DR's of straight line (a, b, c) is perpendicular to DR's of normal to both the planes)

$$\frac{a}{4} = \frac{b}{17} = \frac{c}{5}$$

Now, let the direction ratio of required line be proportional to *l*, *m* and *n*, then its equation be

$$\frac{x-2}{l} = \frac{y-1}{m} = \frac{z-1}{n}$$

where, 2l + m - 5n = 0 and 4l + 17m + 5n = 0

So, 
$$\frac{l}{3} = \frac{m}{-1} = \frac{n}{1}$$

Thus, the required line is  $\frac{x-2}{3} = \frac{y-1}{-1} = \frac{z-1}{1}$ 

• Ex. 76 Does  $\frac{a}{x-y} + \frac{b}{y-z} + \frac{c}{z-x} = 0$  represents a pair

...(iii)

**Sol.** Here, given equation is  $\frac{a}{x-y} + \frac{b}{y-z} + \frac{c}{z-x} = 0$ 

$$\Rightarrow a(y-z)(z-x) + b(x-y)(z-x) + c(x-y)(y-z) = 0$$

$$\Rightarrow$$
  $-axy + ayz - az^2 + axz + bxz - bx^2 - byz$ 

$$+ byx + cxy - cxz - cy^{2} + cyz = 0$$
$$bx^{2} + cy^{2} + az^{2} - (b + c - a)xy -$$

$$bx + cy + az - (b + c - a)xy -$$

$$(c+a-b)yz - (a+b-c)zx = 0$$

∴Value of determinant

$$b -\frac{1}{2}(b+c-a) -\frac{1}{2}(a+b-c)$$

$$-\frac{1}{2}(b+c-a) c -\frac{1}{2}(c+a-b)$$

$$-\frac{1}{2}(a+b-c) \frac{1}{2}(c+a-b) a$$

$$= \begin{vmatrix} 0 & 0 & 0 \\ -\frac{1}{2}(b+c-a) & c & -\frac{1}{2}(c+a-b) \\ -\frac{1}{2}(a+b-c) & -\frac{1}{2}(c+a-b) & a \end{vmatrix}$$
$$[R_1 \to R_1 + R_2 + R_3]$$

Hence, the given equation represents a pair of planes.

• **Ex. 77** If the straight line  $\frac{x-\alpha}{l} = \frac{y-\beta}{m} = \frac{z-\gamma}{n}$  intersect the curve  $ax^2 + by^2 = 1$ , z = 0, then prove that  $a(\alpha n - \gamma l)^2 + b(\beta n - \gamma m)^2 = n^2$ .

Sol. Here,

$$\frac{x-\alpha}{l} = \frac{y-\beta}{m} = \frac{z-\gamma}{n} = \lambda$$

∴ Any point on the given line

$$(\lambda l + \alpha, \lambda m + \beta + \lambda n + y)$$

If it lies on the curve  $ax^2 + by^2 = 1$ , z = 0

$$a(\alpha + l\lambda)^2 + b(\beta + m\lambda)^2 = 1 \qquad ...(i)$$

and

$$\lambda n + \gamma = 0 \qquad \qquad \dots (ii)$$

From Eq. (ii),  $\lambda = \frac{-\gamma}{n}$  must satisfy Eq. (i), we get

$$a\left(\alpha - \frac{l\gamma}{n}\right)^2 + b\left(\beta - \frac{m\gamma}{n}\right)^2 = 1$$
$$a(n\alpha - l\gamma)^2 + b(n\beta - m\gamma)^2 = n^2$$

**Ex. 78** Prove that the three lines from O with direction cosines  $l_1$ ,  $m_1$ ,  $n_1$ ;  $l_2$ ,  $m_2$ ,  $n_2$  and  $l_3$ ,  $m_3$ ,  $n_3$  are coplanar, if  $l_1(m_2n_3 - n_2m_3) + m_1(n_2l_3 - l_2n_3) + n_1(l_2m_3 - l_3m_2) = 0$ .

**Sol.** Here, three given lines are coplanar, if they have common perpendicular.

Let DC's of common perpendicular be *l*, *m* and *n*.

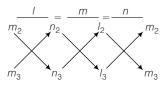

$$ll_1 + mm_1 + nn_1 = 0$$
 ...(i)

$$ll_2 + mm_2 + nn_2 = 0$$
 ...(ii)

d 11 | mm | m = 0

$$ll_3 + mm_3 + nn_3 = 0$$
 ...(iii)

Solving Eqs. (ii) and (iii) by cross multiplication method, we get

$$\Rightarrow \frac{l}{m_2 n_3 - n_2 m_3} = \frac{m}{n_2 l_3 - n_3 l_2} = \frac{n}{l_2 m_3 - l_3 m_2} = 0$$

 $\Rightarrow l = k(m_2n_3 - n_2m_3), m = k(n_2l_3 - n_3l_2), n = k(l_2m_3 - l_3m_2)$ Substituting in Eq. (i), we get

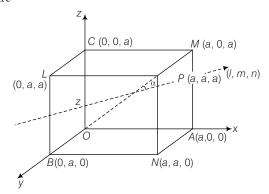

$$k(m_2n_3 - n_2m_3)l_1 + k(n_2l_3 - n_3l_2)m_1 + k(l_2m_3 - l_3m_2)n_2 = 0$$
  

$$\Rightarrow l_1(m_2n_3 - n_2m_2) + m_1(n_2l_3 - n_3l_2) + n_1(l_2m_3 - l_3m_2)$$

The DC's of AL are

The DC's of BM are

The DC's of CN are

• Ex. 83 Find the perpendicular distance of a corner of a unit cube from a diagonal not passing through it.

**Sol.** Let the edges *OA*, *OB*, *OC* of the unit cube be along *OX*, *OY* and OZ, respectively. Since, OA = OB = OC = 1 unit

$$\therefore \qquad OA = \hat{i}, OB = \hat{j}, OC = \hat{k}$$

Let *CM* be perpendicular from the corner *C* on the diagonal *OP*. The vector equation of OP is

$$\mathbf{r} = \lambda(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}})$$

.. 
$$OM = \text{Projection of } \mathbf{OC} \text{ on } \mathbf{OP}$$

$$= \mathbf{OC} \cdot \mathbf{OP}$$

$$= \hat{\mathbf{k}} \frac{(\hat{\mathbf{i}} + \hat{\mathbf{j}} + \hat{\mathbf{k}})}{\sqrt{3}} = \frac{1}{\sqrt{3}}$$
Now,  $OC^2 = OM^2 + CM^2$ 

$$\Rightarrow CM^2 = |OC|^2 - OM^2 = 1 - \frac{1}{3} = \frac{2}{3}$$

$$\Rightarrow CM = \sqrt{\frac{2}{3}}$$

- **Ex. 84** If a variable plane forms a tetrahedron of constant volume  $64k^3$  with the coordinate planes, then find the locus of the centroid of the tetrahedron.
- **Sol.** Let the variable plane intersects the coordinate axes at A(a, 0, 0), B(0, b, 0) and C(0, 0, c). Then, the equation of the plane will be

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1 \qquad \dots (i)$$

Let  $P(\alpha, \beta, \gamma)$  be the centroid of tetrahedron *OABC*, then

$$\alpha = \frac{a}{4}, \beta = \frac{b}{4}, \gamma = \frac{c}{4}$$

or 
$$a = 4\alpha, b = 4\beta, c = 4\gamma$$

 $\Rightarrow$  Volume of tetrahedron =  $\frac{1}{3}$  (Area of  $\triangle AOB$ ) · OC

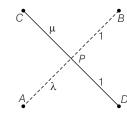

$$\Rightarrow \qquad 64k^3 = \frac{1}{3} \left( \frac{1}{2} ab \right) c = \frac{abc}{6}$$

$$\Rightarrow \qquad 64k^3 = \frac{(4\alpha)(4\beta)(4\gamma)}{6}$$

$$\Rightarrow k^3 = \frac{\alpha\beta\gamma}{6}$$

∴ Required locus of  $P(\alpha, \beta, \gamma)$  is  $xyz = 6k^3$ .

- **Ex. 85** Show that the line segments joining the points (4,7,8), (-1,-2,1) and (2,3,4) (1,2,5) intersect. Verify whether the four points concyclic.

Then,  $P\left(\frac{-\lambda + 4}{\lambda + 1}, \frac{-2\lambda + 7}{\lambda + 1}, \frac{\lambda + 8}{\lambda + 1}\right)$ 

$$= \left(\frac{\mu + 2}{\mu + 1}, \frac{2\mu + 3}{\mu + 1}, \frac{5\mu + 4}{\mu + 1}\right)$$

$$\Rightarrow \frac{-\lambda + 4}{\lambda + 1} = \frac{\mu + 2}{\mu + 1}, \frac{-2\lambda + 7}{\lambda + 1} = \frac{2\mu + 3}{\mu + 1}$$

$$\frac{\lambda + 8}{\lambda + 1} = \frac{5\mu + 4}{\mu + 1}$$

$$\Rightarrow \frac{-(\lambda + 1) + 5}{\lambda + 1} = \frac{(\mu + 1) + 1}{\mu + 1}$$

$$\frac{-2(\lambda + 1) + 9}{\lambda + 1} = \frac{2(\mu + 1) + 1}{\mu + 1}$$

$$\frac{(\lambda + 1) + 7}{\lambda + 1} = \frac{5(\mu + 1) - 1}{\mu + 1}$$

$$\Rightarrow -1 + \frac{5}{\lambda + 1} = 1 + \frac{1}{\mu + 1}$$

$$-2 + \frac{9}{\lambda + 1} = 2 + \frac{1}{\mu + 1};$$

$$1 + \frac{7}{\lambda + 1} = 5 - \frac{1}{(\mu + 1)}$$

Let 
$$\frac{1}{\lambda + 1} = x$$
 and  $\frac{1}{\mu + 1} = y$ 

$$\Rightarrow 5x - y = 2; 9x - y = 4; 7x + y = 4$$

On solving, 
$$x = \frac{1}{2}$$
,  $y = \frac{1}{2}$ 

$$\Rightarrow \lambda + 1 = 2, \mu + 1 = 2$$
$$\lambda = 1, \mu = 1$$

Clearly, if  $\lambda = 1$  and  $\mu = 1$ ,

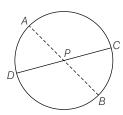

AB and CD bisects each other.

$$\therefore \qquad P = \left(\frac{3}{2}, \frac{5}{2}, \frac{9}{2}\right)$$

Now, 
$$AP = \sqrt{\left(4 - \frac{3}{2}\right)^2 + \left(7 - \frac{5}{2}\right)^2 + \left(8 - \frac{9}{2}\right)^2}$$
  
=  $\frac{\sqrt{155}}{2} = PB$ 

Also, 
$$CP = \sqrt{\left(2 - \frac{3}{2}\right)^2 + \left(3 - \frac{5}{2}\right)^2 + \left(4 - \frac{9}{2}\right)^2}$$
  
=  $\frac{\sqrt{3}}{2} = PD$ 

We know four points A, B, C and D are concylic, if  $AP \cdot PB = PC \cdot PD$

:: O, Q and P are collinear.

$$\therefore \frac{\alpha}{x_1} = \frac{\beta}{y_1} = \frac{\gamma}{z_1} = k$$
 (say) ...(i)

Since,  $P(\alpha, \beta, \gamma)$  lie on the plane

$$lx + my + nz = p,$$

$$l\alpha + m\beta + n\gamma = p$$

Since,  $P(\alpha, \beta, \gamma)$  lie on the plane lx + my + nz = p,  $l\alpha + m\beta + n\gamma \pm p$ 

$$\Rightarrow klx_1 + kmy_1 + knz_1 = p \qquad \text{[using Eq. (i)] ...(ii)}$$

Since,  $OP \cdot OQ = p^2$ 

From Eqs. (ii) and (iii), we get

$$\frac{lx_1 + my_1 + nz_1}{x_1^2 + y_1^2 + z_1^2} = \frac{1}{p}$$

$$\Rightarrow$$

DR's of PQ are  $\alpha - p$ ,  $\beta - q$ ,  $\gamma - r$ .

Since, PQ perpendicular on plane Eq. (iii), we get

$$\therefore \qquad \alpha = p + a'k, \beta = q + b'k, \gamma = r + c'k$$

Putting the values of  $\alpha$ ,  $\beta$  and  $\gamma$  in Eq. (iii), we get

$$\Rightarrow 2(a'p + b'q + c'r + d') = -k(a'^2 + b'^2 + c'^2)$$

Since,  $P(\alpha, \beta, \gamma)$  lies on plane (i), we get

$$a\alpha + b\beta + c\gamma + d = 0$$

$$\Rightarrow a(p + ka') + n(q + kb') + c(r + kc') + d = 0$$

$$\therefore \qquad k = -\frac{(ap + bq + cr + d)}{(aa' + bb' + cc')}$$

Putting the value of k in Eq. (iv), we get

$$2(a'p + b'q + c'r + d')$$

$$=\frac{(a'^2+b'^2+c'^2)(ap+bq+cr+d)}{aa'+bb'+cc'}$$

:.Locus of Q(p, q, r).

i.e. equation reflection of plane (i) in plane (ii) is,

$$2(aa' + bb' + cc')(a'x + b'y + c'z + d')$$

$$\frac{h^2 + k^2 + l^2}{a\alpha} + \frac{h^2 + k^2 + l^2}{b\beta} + \frac{h^2 + k^2 + l^2}{c\gamma}$$

$$= \frac{h}{a} + \frac{k}{b} + \frac{1}{c} = 1$$
 [from Eq. (ii)]

∴ PQ is perpendicular to both OA and BC.

$$l + m + n = 0$$

 $l - m = 0$  ...(vi)

On solving Eqs. (v) and (vi), we get

 $l^2 + m^2 + n^2 = 1$ Also,

**1.** Suppose *xy*-plane divides the line joining the given points in the ratio  $\lambda$ : 1. The coordinate of the point of division are

$$\left(\frac{2\lambda-1}{\lambda+1}, \frac{-5\lambda+3}{\lambda+1}, \frac{6\lambda+4}{\lambda+1}\right)$$

This point lies on xy-plane.

$$\therefore \frac{6\lambda + 4}{\lambda + 1} = 0 \Rightarrow \lambda = -\frac{2}{3}$$

Hence, *xy*-plane divides externally in the ratio 2 : 3.

**Aliter** We know that the xy-plane divides the line segment joining  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  in the ratio  $-z_1 : z_2$ . Therefore, xy-plane divides the segment joining (-1, 3, 4) and (2, -5, 6) in the ratio -4:6 i.e. 2:3 externally.

**2.** Suppose zx-plane divides the join of (1, 2, 3) and (4, 2, 1) in the ratio  $\lambda$ : 1. Then, the co-ordinates of the point of division are

$$\left(\frac{4\lambda+1}{\lambda+1}, \frac{2\lambda+2}{\lambda+1}, \frac{\lambda+3}{\lambda+1}\right)$$

This point lies on zx-plan

$$\therefore \quad y\text{-coordinate} = 0 \Rightarrow \frac{2\lambda + 2}{\lambda + 1} = 0 \Rightarrow \lambda = -1$$

Hence, zx-plane divides the join of (1, 2, 3) and (4, 2, 1)externally in the ratio 1:1.

**Aliter** We know that the *zx*-plane divides the segment joining  $P(x_1, y_1, z_1)$  and  $Q(x_2, y_2, z_2)$  in the ratio  $-y_1 : y_2$ .  $\therefore zx$ -plane divides the join of (1, 2, 3) and (4, 2, 1) in the ratio -2:2 i.e. 1:1 externally.

**3.** Suppose *R* divides *PQ* in the ratio  $\lambda$  : 1. Then, the coordinates of R are

$$\left(\frac{5\lambda+3}{\lambda+1}, \frac{4\lambda+2}{\lambda+1}, \frac{-6\lambda-4}{\lambda+1}\right)$$

But, the coordinates of R are given as (9, 8, -10).

$$\therefore \frac{5\lambda + 3}{\lambda + 1} = 9, \quad \frac{4\lambda + 2}{\lambda + 1} = 8$$
and
$$\frac{-6\lambda - 4}{\lambda + 1} = -10 \implies \lambda = -\frac{3}{2}$$

Hence, R divides PQ externally in the ratio 3:2.

**4.** *D* divides *BC* in the ratio *AB* : *AC* i.e. 3 : 13. Therefore, coordinates of D are

$$\left(\frac{3\times -9 + 13\times 5}{3+13}, \frac{3\times 6 + 13\times 3}{3+13}, \frac{3\times -3 + 13\times 2}{3+13}\right) \text{ or } \left(\frac{19}{8}, \frac{57}{16}, \frac{17}{16}\right).$$

**5.** Let l, m, n be the direction cosines of the given line. Then, as it makes an acute angle with *x*-axis. Therefore, l > 0. The line passes through (6, -7, -1) and (2, -3, 1). Therefore, its direction ratios are

$$6-2$$
,  $-7+3$ ,  $-1-1$  or  $4$ ,  $-4$ ,  $-2$  or  $2$ ,  $-2$ ,  $-1$ 

Hence, direction cosines of the given line are  $\frac{2}{3}$ ,  $-\frac{2}{3}$ ,  $-\frac{1}{3}$ 

**6.** We have,  $\alpha = 45^{\circ}$  and  $\beta = 60^{\circ}$ 

Suppose **OP** makes angle  $\gamma$  with OZ. Then,  $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$ 

$$\Rightarrow \qquad \left(\frac{1}{\sqrt{2}}\right)^2 + \left(\frac{1}{2}\right)^2 + \cos^2 \gamma = 1$$

$$\Rightarrow \qquad \cos^2 \gamma = \frac{1}{4} \Rightarrow \cos \gamma = \pm \frac{1}{2}$$

$$\Rightarrow \qquad \qquad y = 60^{\circ}, 120^{\circ}$$

**7.** Let *OA* and *OB* be two lines with direction  $l_1$ ,  $m_1$ ,  $n_1$  and  $l_2, m_2, n_2$ .

Let OA = OB = 1. Then, the coordinates of A and B are  $(l_1, m_1, n_1)$  and  $(l_2, m_2, n_2)$  respectively. Let OC be the bisector of  $\angle$  *AOB*. Then, *C* is the mid point of *AB* and so its coordinates

$$\left(\frac{l_{1}+l_{2}}{2},\frac{m_{1}+m_{2}}{2},\frac{n_{1}+n_{2}}{2}\right)$$

$$B\left(-l_{2},m_{2},n_{2}\right)$$

$$C\left(\frac{l_{1}+l_{2}}{2},\frac{m_{1}+m_{2}}{2},\frac{n_{1}+n_{2}}{2}\right)$$

$$A\left(-l_{1},m_{1},n_{1}\right)$$

$$X' \longrightarrow E\left(\frac{l_{1}+l_{2}}{2},\frac{m_{1}+m_{2}}{2},\frac{n_{1}+n_{2}}{2}\right)$$

$$D\left(-l_{2},-m_{2},-n_{2}\right)$$

$$\therefore \text{Direction ratios of } OC \text{ are } \frac{l_1 + l_2}{2}, \frac{m_1 + m_2}{2}, \frac{n_1 + n_2}{2}$$

$$Now, \qquad OC = \sqrt{\left(\frac{l_1 + l_2}{2}\right)^2 + \left(\frac{m_1 + m_2}{2}\right) + \left(\frac{n_1 + n_2}{2}\right)^2}$$

$$OC = \frac{1}{2}$$

$$\sqrt{(l_1^2 + m_1^2 + n_1^2) + (l_2^2 + m_2^2 + n_2^2) + 2(l_1l_2 + m_1m_2 + n_1n_2)}$$

$$\Rightarrow \qquad OC = \frac{1}{2}\sqrt{2 + 2\cos\theta} \quad [\because \cos\theta = l_1l_2 + m_1m_2 + n_1n_2]$$

$$\Rightarrow \qquad OC = \frac{1}{2}\sqrt{2 + 2\cos\theta} = \cos\left(\frac{\theta}{2}\right)$$

.. Direction cosines of **OC** are

or, 
$$\frac{l_1 + l_2}{2(OC)}, \frac{m_1 + m_2}{2(OC)}, \frac{n_1 + n_2}{2(OC)}$$

$$\frac{l_1 + l_2}{2(\cos\frac{\theta}{2})}, \frac{m_1 + m_2}{2(\cos\frac{\theta}{2})}, \frac{n_1 + n_2}{(2\cos\frac{\theta}{2})}$$

**8.** The given line is parallel to the vector  $\mathbf{n} = \hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ . The required plane passes through the point (2, 3, 1) i.e.,  $2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + \hat{\mathbf{k}}$ and is perpendicular to the vector  $\mathbf{n} = \hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ . So, its

$$\{\mathbf{r} - (2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + \hat{\mathbf{k}})\} \cdot (\hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}) = 00000$$

$$\Rightarrow \qquad \mathbf{r} \cdot (\hat{\mathbf{i}} - \hat{\mathbf{j}} + 2\hat{\mathbf{k}}) = 1$$

251

$$PA^{2} - PB^{2} = k$$
 (constant)  

$$\Rightarrow |\mathbf{AP}|^{2} - |\mathbf{BP}|^{2} = k$$
  

$$\Rightarrow |\mathbf{r} - \mathbf{a}|^{2} - |\mathbf{r} - \mathbf{b}|^{2} = k$$
  

$$\Rightarrow \{|\mathbf{r}|^{2} + |\mathbf{a}|^{2} - 2\mathbf{r} \cdot \mathbf{a}\} - \{|\mathbf{r}|^{2} + |\mathbf{b}|^{2} - 2\mathbf{r} \cdot \mathbf{b}\} = k$$
  

$$\Rightarrow 2\mathbf{r} \cdot (\mathbf{b} - \mathbf{a}) = k + |\mathbf{b}|^{2} - |\mathbf{a}|^{2}$$
  

$$\Rightarrow \mathbf{r} \cdot (\mathbf{b} - \mathbf{a}) = \lambda, \text{ where } \lambda = \frac{1}{2} \{k + |\mathbf{b}|^{2} - |\mathbf{a}|^{2} \}$$

Clearly, it represents a plane.

**10.** The position vectors of two given points are  $\mathbf{a} = \hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  and  $\mathbf{b} = 3\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  and the equation of the given plane is

$$\mathbf{r} = (5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 7\hat{\mathbf{k}}) + 9 = 0$$
or
$$\mathbf{r} \cdot \mathbf{n} + d = 0$$
We have
$$\mathbf{a} \cdot \mathbf{n} + d = (\hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}) \cdot (5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 7\hat{\mathbf{k}}) + 9$$

$$= 5 - 2 - 21 + 9 < 0$$
and
$$\mathbf{b} \cdot \mathbf{n} + d = (3\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 3\hat{\mathbf{k}}) \cdot (5\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - 7\hat{\mathbf{k}}) + 9$$

$$= 15 + 6 - 21 + 9 > 0$$

So, the points **a** and **b** are on the opposite sides of the plane.

$$\mathbf{r} \cdot (4\hat{\mathbf{i}} - 12\hat{\mathbf{j}} - 3\hat{\mathbf{k}}) - 7 = 0 \text{ is,}$$
  
 $\mathbf{r} \cdot (4\hat{\mathbf{i}} - 12\hat{\mathbf{j}} - 3\hat{\mathbf{k}}) + \lambda = 0$ 

This passes through  $2\hat{\mathbf{i}} - \hat{\mathbf{j}} - 4\hat{\mathbf{k}}$ 

$$\therefore (2\hat{\mathbf{i}} - \hat{\mathbf{j}} - 4\hat{\mathbf{k}}) \cdot (4\hat{\mathbf{i}} - 12\hat{\mathbf{j}} - 3\hat{\mathbf{k}}) + \lambda = 0$$

$$\Rightarrow 8 + 12 + 12 + \lambda = 0$$

$$\Rightarrow \qquad \qquad \lambda = -32$$

So, the required plane is  $\mathbf{r} \cdot (4\hat{\mathbf{i}} - 12\hat{\mathbf{j}} - 3\hat{\mathbf{k}}) - 32 = 0$

Since, three planes have a common line of intersection the above equation should be identical with  $\mathbf{r} \cdot \mathbf{n}_3 = p_3$  for some  $\lambda$ . That is for some  $\lambda$ ,

$$\mathbf{n}_1 + \lambda \mathbf{n}_2 = k\mathbf{n}_3 \qquad \dots (i)$$

 $p_1 + \lambda p_2 = k p_3$ and ...(ii)

From Eq. (i)

$$p_1(\mathbf{n}_2 \times \mathbf{n}_3) + p_2\lambda(\mathbf{n}_2 \times \mathbf{n}_3) + p_3(\mathbf{n}_1 + \mathbf{n}_2) = 0$$

$$\Rightarrow p_1(\mathbf{n}_2 \times \mathbf{n}_3) + p_2(\mathbf{n}_3 \times \mathbf{n}_1) + p_3(\mathbf{n}_1 \times \mathbf{n}_2) = 0$$

**48.** Equation of any plane through the intersection of  $\mathbf{r} \cdot \mathbf{n}_1 = q_1$ and  $\mathbf{r} \cdot \mathbf{n}_2 = q_2$  is of the form

$$\mathbf{r} \cdot \mathbf{n}_1 + \lambda \mathbf{r} \cdot \mathbf{n}_2 = q_1 + \lambda q_2 \qquad \dots (i)$$

where  $\lambda$  is a parameter.

So,  $\mathbf{n}_1 + \lambda \mathbf{n}_2$  is normal to the plane (i). Now, any plane parallel to the line of intersection of the planes  $\mathbf{r} \cdot \mathbf{n}_3 = q_3$  and  $\mathbf{r} \cdot \mathbf{n}_4 = q_4$  is of the form.

 $\mathbf{r} \cdot (\mathbf{n}_3 + \mu \mathbf{n}_4) = q_3 + \mu q_4$ , hence we must have

$$\mathbf{n}_1 + \lambda \mathbf{n}_2 = k(\mathbf{n}_3 + \mu \mathbf{n}_4) \text{ for some } k$$

$$\Rightarrow \qquad [\mathbf{n}_1 + \lambda \mathbf{n}_2] \cdot [\mathbf{n}_3 \times \mathbf{n}_4] = 0$$

$$\Rightarrow \qquad [\mathbf{n}_1 \ \mathbf{n}_3 \ \mathbf{n}_4] + \lambda [\mathbf{n}_2 \ \mathbf{n}_3 \ \mathbf{n}_4] = 0$$

$$\Rightarrow \qquad \lambda = -\frac{[\mathbf{n}_1 \ \mathbf{n}_3 \ \mathbf{n}_4]}{[\mathbf{n}_2 \ \mathbf{n}_3 \ \mathbf{n}_4]}$$

$$\Rightarrow \qquad \lambda = -\frac{[\mathbf{n}_1 \ \mathbf{n}_3 \ \mathbf{n}_4]}{[\mathbf{n}_2 \ \mathbf{n}_3 \ \mathbf{n}_4]}$$

On putting this value in Eq. (i), we have the equation of required plane as

$$\mathbf{r} \cdot \mathbf{n}_1 - q_1 = \frac{[\mathbf{n}_1 \ \mathbf{n}_3 \ \mathbf{n}_4]}{[\mathbf{n}_2 \ \mathbf{n}_3 \ \mathbf{n}_4]} (r \cdot \mathbf{n}_2 - q_2)$$

$$\Rightarrow [\mathbf{n}_2 \ \mathbf{n}_3 \ \mathbf{n}_4] (\mathbf{r} \cdot \mathbf{n}_1 - q_1)$$

$$= [\mathbf{n}_1 \ \mathbf{n}_3 \ \mathbf{n}_4] (\mathbf{r} \cdot \mathbf{n}_2 - q_2)$$

Eq. (i) lies in x + y + cz = d

$$1 + 0 + c = d$$
$$1 + c = d$$

Also, 
$$1 \cdot 1 + 1 \cdot 3 + c(-1) = 0$$

$$c = 4$$

$$\therefore 1 + 4 = d \implies d = 5$$

Hence, actual volume with unit vectors

Now, 
$$|\mathbf{a} \times \mathbf{b}| = \sqrt{a^2b^2 - (\mathbf{a} \cdot \mathbf{b})^2} = \sqrt{4 - 1} = \sqrt{3}$$

**77.** If the given vectors are coplanar, then  $\begin{vmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ x_3 & y_3 & z_3 \end{vmatrix} = 0$ 

The set of equation

$$x_1x + y_1y + z_1z = 0$$
  
$$x_2x + y_2y + z_2z = 0$$

$$x_3x + y_3y + z_3z = 0$$

has a non-trivial solution.

Let the given set has a non-trivial solution x, y, z without loss of generality, we can assume that  $x \ge y \ge z$ .

For the given equation  $x_1x + y_1y + z_1z = 0$ , we have

$$x_{1}x = -y_{1}y - z_{1}z$$

$$\Rightarrow |x_{1}x| = |y_{1}y + z_{1}z| \le |y_{1}y| + |z_{1}z|$$

$$\Rightarrow |x_{1}x| \le |y_{1}x| + |z_{1}x|$$

$$\Rightarrow |x_{1}| < |y_{1}| + |z_{1}|$$

Which is a contradiction to the given inequality.

$$|x_1| > |y_1| + |z_1|$$

Similarly, the other inequalities rule out the possibility of a non-trivial solution.

Therefore, the given equations have only a trivial solution. So, the given vectors are non-coplanar.

**78.** The vectors  $\mathbf{n}_1 \times \mathbf{n}_2$ ,  $\mathbf{n}_2 \times \mathbf{n}_3$  and  $\mathbf{n}_3 \times \mathbf{n}_1$  are non-coplanar vectors, so every vector can be written as

$$\mathbf{r} = a(\mathbf{n}_1 \times \mathbf{n}_2) + b(\mathbf{n}_2 \times \mathbf{n}_3) + c(\mathbf{n}_3 \times \mathbf{n}_1)$$

Substituting this value in  $\mathbf{r} \cdot \mathbf{n}_1 = q_1$ ,  $\mathbf{a}$ ,  $\mathbf{b}$ , we get

$$a(\mathbf{n}_1 \times \mathbf{n}_2) \cdot \mathbf{n}_1 + b(\mathbf{n}_2 \times \mathbf{n}_3) \cdot \mathbf{n}_1 + c(\mathbf{n}_3 \times \mathbf{n}_1) \cdot \mathbf{n}_1 = q_1$$

$$b(\mathbf{n}_1 \ \mathbf{n}_2 \ \mathbf{n}_3) = q_1 \implies b = \frac{q_1}{\mathbf{n}_1 \ \mathbf{n}_2 \ \mathbf{n}_3}$$

Since, the required point of intersection will have the position vector.

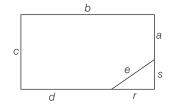

$$\mathbf{r} = \frac{1}{(\mathbf{n}_1 \ \mathbf{n}_2 \ \mathbf{n}_3)} \quad [q_3(\mathbf{n}_1 \times \mathbf{n}_2) + q_1(\mathbf{n}_2 \times \mathbf{n}_3) + q_2(\mathbf{n}_3 \times \mathbf{n}_1)]$$

⇒ Plane is 
$$2x + y + z - 1 - \frac{2}{3}(3x + y + 2z - 2) = 0$$

or y - z + 1 = 0. The required SD must be distance of this plane from any point on the line x = y = z say (1, 1, 1)

$$a = 3\lambda, b = -2\lambda \text{ and } c = 6\lambda$$

and from (i), we have

$$9\lambda^2 + 4\lambda^2 + 36\lambda^2 = (63)^2$$

$$\Rightarrow 49\lambda^2 = (63)^2$$

**114.** Direction ratios of AB are 4 - 2, 5 - 3, 10 - 4 or 1, 1, 3. So AB in parallel to the vector  $\hat{\mathbf{i}} + \hat{\mathbf{j}} + 3\hat{\mathbf{k}}$  and passes through B (2, 3, 4), the vector  $2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}}$ , its equation is

$$2\hat{\mathbf{i}} + 3\hat{\mathbf{j}} + 4\hat{\mathbf{k}} + \lambda(\hat{\mathbf{i}} + \hat{\mathbf{j}} + 3\hat{\mathbf{k}})$$

Similarly, BC passes through the points B (2, 3, 4) and its direction ratios are 2 - 1, 3 - 2, 4 + 1 or 1, 1, 5.

So its cartesian equation is

$$\frac{x-2}{1} = \frac{y-3}{1} = \frac{z-4}{5}$$

Next, if *D* is (*a*, *b*, *c*), then since *ABCD* is a parallelogram mid point of AC and BD is same. (diagonals of a parallelogram bisect each other)

$$\Rightarrow \left(\frac{a+2}{2}, \frac{b+3}{2}, \frac{c+4}{2}\right) = \left(\frac{5}{2}, \frac{7}{2}, \frac{9}{2}\right)$$

$$\Rightarrow$$
  $(a, b, c) = (3, 4.5)$ 

AB is not perpendicular to BC because

$$1 \times 1 + 1 \times 1 + 3 \times 5 \neq 0.$$

ABCD is not a rectangle.

**115.** The coordinates of *P* where the line x = y = z meets the plane x + y + z = 1 are (1/3, 1/3, 1/3) and the co-ordinates of R and S where the line meets the sphere  $x^2 + y^2 + z^2 = 1$  are  $(1/\sqrt{3}, 1/\sqrt{3}, 1/\sqrt{3})$  and  $(-1/\sqrt{3}, -1/\sqrt{3}, -1/\sqrt{3})$ 

So that 
$$PR = \sqrt{3} \left| \left( \frac{1}{3} - \frac{1}{\sqrt{3}} \right) \right| = \sqrt{3} \left( \frac{1}{\sqrt{3}} - \frac{1}{3} \right)$$

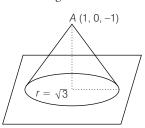

and 
$$PS = \sqrt{3} \left( \frac{1}{3} + \frac{1}{\sqrt{3}} \right)$$

$$\Rightarrow PR \cdot PS = 3\left(\frac{1}{3} - \frac{1}{9}\right) = \frac{2}{3}$$

$$PR + PS = 2$$
  
and  $RS = \sqrt{(1/\sqrt{3} + 1/\sqrt{3})^2 \times 3} = 2$ 

So that, 
$$PR + PS = RS$$

The distance of point A(1, 0, -1) from the plane is  $\frac{|1-2+4|}{\sqrt{9}} = 1$  unit.

The slant height l of the cone is 2 units.

Then the radius of the base of the cone is

$$\sqrt{l^2 - 1} = \sqrt{4 - 1} = \sqrt{3}.$$

Hence, the volume of the cone is  $\frac{\pi}{2}(\sqrt{3})^2 \cdot 1 = \pi$  cubic units.

Area of the circle on the plane which the rod traces is  $3\pi$ . Also, the centre of the circle is Q(x, y, z).

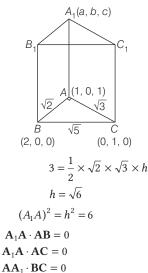

Then

$$\Rightarrow \qquad l - 3m - n = \frac{5}{3} \to \text{(iii)}$$

$$x^{2}y^{2} + y^{2}z^{2} + z^{2}x^{2} = \frac{16}{r^{2}}x^{2}y^{2}z^{2}$$

$$\left(\frac{1}{x}\right)^2 + \left(\frac{1}{y}\right)^2 + \left(\frac{1}{z}\right)^2 = \frac{16}{p^2}$$

 $[\cos^2\alpha\cos^2\beta+\cos^2\alpha\sin^2\beta+\sin^2\alpha]$

- **125.** Statement I  $PA \cdot PB = 9 > 0$ 
  - $\therefore P$  is exterior to the sphere

Statement II is true (standard result)

  $-3y - 2z = 2, 3x + z = -1, 2x - y = 0$ 

i.e. 
$$-6x - 2z = 2$$
,  $3x + z = 1$ .

∴Straight line 
$$2x - y = 0$$
,  $3x + z = -1$ 

#### Statement I

$$\mathbf{r} \times (2\mathbf{i} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}) = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ x & y & z \\ 2 & -1 & 3 \end{vmatrix}$$

= 
$$\hat{\mathbf{i}}(3y + z) - \hat{\mathbf{j}}(3x - 2z) + \hat{\mathbf{k}}(-x - 2y)$$

263

$$\therefore 3y + z = 3, 3x - 2z = 0, -x - 2y = 1$$

$$3x - 2(3 - 3y) = 0$$

$$3x + 6y = 6$$
$$x + 2y = 2$$

Now, 
$$x + 2y = -1$$
,  $x + 2y = 2$  are parallel planes.

 $\mathbf{r} \times (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}) = 3\hat{\mathbf{i}} + \hat{\mathbf{k}}$  is not a straight line.

**127.** 
$$\sin\theta = \left| \frac{2-3+2}{\sqrt{4+9+4\sqrt{3}}} \right| = \frac{1}{\sqrt{51}}$$

∴Statement I is true, Statement II is true by definition.

#### 128. Statement I

$$3y - 4z = 5 - 2k$$
$$-2y + 4z = 7 - 3k$$

$$\therefore x = k, y = 12 - 5k, z = \frac{31 - 13k}{4}$$
 is a point on the line for all

real value of k.

Statement I is true.

**Statement II** Direction ratios of the straight line are < bc' - kbc, kac - ac', 0 > direction ratios of normal to be plane < 0, 0, 1 >

Now, 
$$0 \times (bc' - kbc) + 0 \times (kac - ac') + 1 \times 0 = 0$$

∴The straight line is parallel to the plane.

Statement II is the true but does not explain Statement I.

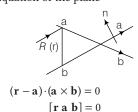

- **129.** Equation of the plane, perpendicular to the plane *P* and containing line L is 8x + y 7z = 4.
- **130.**  $L_1$  and  $L_2$  are obviously not parallel.

Consider the determinent

$$D = \begin{vmatrix} 2 & -4 & 1 \\ 2 & 4 & -3 \\ 1 & 3 & 2 \end{vmatrix}$$
$$= 2(8+9) + 4(4+3) + 1(6-4)$$
$$= 34 + 28 + 2$$
$$D \neq 0 \implies \text{Skew}$$

Hence, Statement I is false.

#### **131.** $\mathbf{n} = \mathbf{a} \times \mathbf{b}$ . Equation of the plane

**132.** Statement II is not true because image of *P* in a plane is a point M such that PM is perpendicular to the plane and the mid-point of PM lies on the plane.

The point A, B, C are respectively (-a, b, c), (a, -b, c) and

which lie on the plane  $\frac{x}{a} + \frac{y}{b} + \frac{z}{a} = 1$  and thus Statement I is

**133.** In Statement II, let **r** be the position vector of the point on the locus, then

$$|\mathbf{r} - \mathbf{a}| = |\mathbf{r} - \mathbf{b}| \implies (\mathbf{r} - \mathbf{a})^2 = (\mathbf{r} - \mathbf{b})^2$$

$$\Rightarrow |\mathbf{r}|^2 + |\mathbf{a}|^2 - 2\mathbf{r} \cdot \mathbf{a} = |\mathbf{r}|^2 + |\mathbf{b}|^2 - 2\mathbf{r} \cdot \mathbf{b}$$
  
$$\Rightarrow 2\mathbf{r} \cdot (\mathbf{a} - \mathbf{b}) + |\mathbf{b}|^2 - |\mathbf{a}|^2 = 0$$

$$\Rightarrow 2\pi \cdot (a - b) + |b| - |a| = 0$$

$$\Rightarrow 2\mathbf{r} \cdot (\mathbf{a} - \mathbf{b}) + (\mathbf{b} - \mathbf{a}) \cdot (\mathbf{b} + \mathbf{a}) = 0$$

$$\Rightarrow 2\mathbf{r} \cdot (\mathbf{a} - \mathbf{b}) + (\mathbf{b} - \mathbf{a}) \cdot (\mathbf{b} + \mathbf{a}) = 0$$

$$\Rightarrow \left(\mathbf{r} - \frac{\mathbf{a} + \mathbf{b}}{2}\right) \cdot (\mathbf{a} - \mathbf{b}) = 0$$

Showing that Statement II is true using it for Statement I.

we get the required locus as

$$\begin{bmatrix} \mathbf{r} - \frac{3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 5\hat{\mathbf{k}} + \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + \hat{\mathbf{k}}}{2} \end{bmatrix}$$

$$(3\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 5\hat{\mathbf{k}} - (\hat{\mathbf{i}} + 2\hat{\mathbf{j}} - \hat{\mathbf{k}}) = 0$$

$$\Rightarrow [\mathbf{r} - (2\hat{\mathbf{i}} + 2\hat{\mathbf{k}}) \cdot (2\hat{\mathbf{i}} - 4\hat{\mathbf{j}} + 6\hat{\mathbf{k}})] = 0$$

$$\Rightarrow \mathbf{r} \cdot (\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + 3\hat{\mathbf{k}}) = 2 \times 1 - 0 \times 2 + 2 \times 3 = 8$$

and thus Statement I is also true.

**134.** Since **a** and **c** are non-collinear. Equating the coefficients of **a** and  $\mathbf{c}$  in the two values of  $\mathbf{r}$  we get.

$$6 - \lambda = 1 + \mu$$
,  $2\lambda - 1 = 3\mu - 1 \implies \lambda = 3$ ,  $\mu = 2$ 

So there exist values for  $\lambda$  and  $\mu$  such that the two values of rare same showing that the lines intersect and hence they are coplanar. Thus, statement I and statement II both are true and the first follows from the second.

 $1-2 \quad 0+1 \quad -1-0 \quad | \quad -1 \quad 1 \quad -1 |$ **135.** Since,

The lines in Statement I are coplanar and equation of the plane containing them is

$$\begin{vmatrix} x-1 & y & z+1 \\ 1 & -1 & 1 \\ 1 & 2 & 3 \end{vmatrix} = -(5x+2y-3z-8) = 0$$

So Statement I is true.

Also, Statement II is true because  $\frac{1}{3} = \frac{2}{6} = \frac{3}{6}$  and 1 + 2 - 3 = 0

But does not lead to Statement I.

- **136.** Any point on the first line is  $(2x_1 + 1, x_1 3, -3x_1 + 2)$ . Any point on the second line is  $(y_1 + 2, -3y_1 + 1, 2y_1 - 3)$ If two lines are coplanar, then  $2x_1 - y_1 = 1$ ,  $x_1 + 3y_1 = 4$  and  $3x_1 + 2y_1 = 5$  are consistent.
- **137.** The direction cosines of segment *OA* are  $\frac{2}{\sqrt{14}}$ ,  $\frac{1}{\sqrt{14}}$  and  $\frac{-3}{\sqrt{14}}$  $OA = \sqrt{14}$

This means OA will be normal to the plane and the equation of the plane is 2x + y - 3z = 14.

**138.** If *l*, *m*, *n* denote the direction ratios of  $L_1$  and l + m - n = 0 and  $l - 3m + 3n = 0 \Longrightarrow l = 0, m = n$ 

 $\Rightarrow$  direction ratios of  $L_1$  are 0, 1, 1 similarly for  $L_2$  and  $L_3$ , we find that the direction ratios of both are 0, 1, 1 showing that  $L_1$ ,  $L_2$ ,  $L_3$  are parallel, thus Statement I is False.

Statement II is True, because solving the given equation we get x = 0, y - z = -1 and  $y - z = \frac{-2}{3}$  which is not possible.

$$k \neq -9, -\frac{6}{5}, 5$$

 $k = \frac{5}{6}$  and 0 will be the values for which  $L_1$ ,  $L_2$  and  $L_3$  form a triangle

#### **179.** Given, $\frac{abc}{6} = 32$ , where A, B and C are respectively, (a, 0, 0), (0, b, 0), (0, 0, c).

(A) Centroid of tetrahedron 
$$[\alpha, \beta, \gamma] = \left(\frac{a}{4}, \frac{b}{4}, \frac{c}{4}\right)$$

$$a = 4\alpha$$
,  $b = 4\beta$ ,  $c = 4\gamma$ 

$$64\alpha\beta\gamma = 32 \times 6$$

$$\alpha\beta\gamma =$$

(B) Equidistant point 
$$(\alpha, \beta, \gamma) = \left(\frac{a}{2}, \frac{b}{2}, \frac{c}{2}\right)$$

$$a = 2\alpha, b = 2\beta, c = 2\gamma$$
  
 $8\alpha\beta\gamma = 32 \times 6$   
 $\alpha\beta\gamma = 24$ 

(C) The equation of the plane is  $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$ 

∴Foot of the perpendicular from the origin

$$\equiv (\alpha, \beta, \gamma) \equiv \left(\frac{1/a}{\sum 1/a^2}, \frac{1/b}{\sum 1/b^2}, \frac{1/c}{\sum 1/c^2}\right)$$

$$\frac{1}{a\alpha} = \frac{1}{b\beta} = \frac{1}{c\gamma} = t$$

where, 
$$t = \frac{1}{a^2} + \frac{1}{b^2} + \frac{1}{c^2} = \sum \frac{1}{a^2}$$

or 
$$t = (\alpha^2 + \beta^2 + \gamma^2)t^2$$

$$t = \frac{1}{\alpha^2 + \beta^2 + \gamma^2}$$

and 
$$\alpha = \frac{\alpha^2 + \beta^2 + \gamma^2}{\alpha}, b = \frac{\alpha^2 + \beta^2 + \gamma^2}{\beta},$$

$$c = \frac{\alpha^2 + \beta^2 + \gamma^2}{\gamma}$$

Now, 
$$abc = 6 \times 32$$
  
 $(\alpha^2 + \beta^2 + \gamma^2) = 192 \alpha\beta\gamma$ 

(D) Let P be  $(\alpha, \beta, \gamma)$ , then  $PA \perp PB$ 

$$\Rightarrow a(\alpha - a) + \beta(\beta - b) + \gamma \gamma = 0$$

$$\Rightarrow a\alpha + b\beta = \alpha^2 + \beta^2 + \gamma^2$$

$$PB \perp PC$$

$$\Rightarrow$$
  $a\alpha + b(\beta - b) + c(\gamma - c) = 0$ 

$$\Rightarrow$$
  $b\beta + c\gamma = \alpha^2 + \beta^2 + \gamma^2$ 

$$\therefore \frac{a}{1/\alpha} = \frac{b}{1/\beta} = \frac{c}{1/\gamma}$$

$$a = \frac{\alpha^2 + \beta^2 + \gamma^2}{2\alpha}, b = \frac{\alpha^2 + \beta^2 + \gamma^2}{2\beta}$$

and 
$$c = \frac{\alpha^2 + \beta^2 + \gamma^2}{2\gamma}$$

$$\therefore$$
  $abc = 6 \times 32$ 

$$\Rightarrow \qquad (\alpha^2 + \beta^2 + \gamma^2) = 192 \times 8\alpha\beta\gamma$$

$$=1536\alpha\beta\gamma$$

**180.** Let *O*(0, 0, 0), *A*(3, 4, 7) and *B*(5, 2, 6) be the given point

Area of 
$$\triangle OAB = \frac{1}{2}OA \cdot OB \sin(\angle AOB)$$

Now, 
$$OA = \sqrt{3^2 + 4^2 + 7^2} = \sqrt{74}$$
  
 $OB = \sqrt{5^2 + 2^2 + 6^2} = \sqrt{65}$ 

Also dc's of the line *OA* and *OB* are

$$=\frac{3}{\sqrt{74}}, \frac{4}{\sqrt{74}}, \frac{7}{\sqrt{74}} \text{ and } \frac{5}{\sqrt{65}}, \frac{2}{\sqrt{65}}, \frac{6}{\sqrt{65}}$$

$$\therefore$$
 Required area  $\frac{1}{2} \times \sqrt{74} \times \sqrt{65} \times \frac{3}{\sqrt{74}} = \frac{3}{2}\sqrt{65}$ 

(B) Let the required sphere be

 $x^{2} + y^{2} + z^{2} + 2ux + 2vy + wz + d = 0$  ...(1) substituting given points then we get 1 + 2u + d = 0

$$1 + 2v + d = 0$$
 and  $1 + 2w + d = 0$ 

$$u = v = w = \frac{1+d}{2}$$

If *R* be the radius of the sphere,

then 
$$R^2 = u^2 + v^2 + w^2 - d$$

covert above equation in terms of d differentiate, equate to zero solve for d.

(C) Let the given points be *A*, *B* and *C* respectively.

Then find AB, AC, BC and then apply  $AB^2 + AC^2 = BC^2$  then solve for the  $\lambda$ .

(D) Any point on the line is (1 - r, r + 1, r)

The direction ratio of the line joining (1, 3, 4) & (1 - r, r + 1, r) is -r, r - 2, r - 4

$$\therefore (-1)(-r) + 1 \cdot (r-2) + (r-4) = 0$$
$$r + r - 2 + r - 4 = 0$$
$$3r = 6 \implies r = 2$$

∴ Foot of the perpendicular is (-1, 3, +2)

∴ Distance = 
$$\sqrt{(2)^2 + 0 + 4} = 2\sqrt{2}$$

$$d = 2\sqrt{2}$$

$$\frac{d}{2\sqrt{3}} = \frac{2\sqrt{2}}{2\sqrt{3}} = \frac{\sqrt{2}}{\sqrt{3}}$$

$$\Rightarrow \qquad \cos\theta = \frac{a^2 + a^2 - a^2}{\sqrt{3a^2} \times \sqrt{3a^2}} \frac{1}{3} \Rightarrow \theta = \cos^{-1} \frac{1}{3}$$

Let us take the solid diagonal as the one joining (0, 0, 0) (a, a, a) and plane diagonal as joining (0, 0, 0) and (a, a, 0). We easily get the angle as  $\cos^{-1} \frac{2}{\sqrt{6}}$ .

The third part is easily found as  $\cos^{-1}\left(\frac{1}{2}\right)$ 

Hence, matching follows (A)  $\rightarrow$  (r); (B)  $\rightarrow$  (p); (C)  $\rightarrow$  (q)

**182.** (i) Shortest distance

$$= \frac{(-6, -15, 3) \cdot (-6, -15, 3)}{\sqrt{36 + 225 + 9}}$$

$$\lambda = 3$$

**186.** Given planes are

$$x - cy - bz = 0$$
 ...(i)  
 $cx - y + az = 0$  ...(ii)

Equation of plane passing through the line of intersection of planes (i) and (ii) may be taken as

$$(x - cy - bz) + \lambda (cx - y + az) = 0 \qquad \dots (iv)$$

Now, eliminating  $\lambda$  we get

$$a^2 + b^2 + c^2 + 2abc = 1$$

**187.** We must have  $\frac{\lambda(-1) + 1 \times 3}{\lambda + 1} = 0 \implies \lambda = 3$

 $\Rightarrow$  Shortest distance = 2

**191.** The point  $(-1, \lambda, -2)$  must be lie on the plane

$$2x - 2y + z + 12 = 0$$
$$-2 - 2\lambda - 2 + 12 = 0$$
$$\lambda = 4$$

We can easily show that the distance of (-1, 4, -2) from centre of the sphere (1, 2, -1) is equal to its radius.

**192.** 
$$1 = \frac{a+1+2+0}{4}$$

$$\sqrt{1^2 + 25 + 49} = \sqrt{75} = 5\sqrt{3} \implies \lambda = 3$$

**193.** Equating the distances of circumcentre  $(-1, \lambda, -3)$  from

$$(3, 2, -5)$$
 and  $(-3, 8, -5)$  we get

$$2^{2} + (\lambda + 2)^{2} + (-3 + 5)^{2} = (-1 + 3)^{2} + (\lambda - 8)^{2} + (-3 + 5)^{2}$$

Note: Verify

(i)  $(-1, \lambda, -3)$  is at the same distance from third vertex.

(ii)  $(-1, \lambda, -3)$  lies on the plane containing three points

**195.** A plane containing line of intersection of the given planes is

$$x - y - z - 4 + \lambda(x + y + 2z - 4) = 0$$

i.e., 
$$(\lambda + 1)x + (\lambda - 1)y + (2\lambda - 1)z - 4(\lambda + 1) = 0$$

vector normal to it

$$V = (\lambda + 1) \hat{\mathbf{i}} + (\lambda - 1) \hat{\mathbf{j}} + (2\lambda - 1) \hat{\mathbf{k}}$$

Now the vector along the line of intersection of the planes

$$2x + 3y + z - 1 = 0$$

$$x + 3y + 2z - 2 = 0$$
 is given by

$$\mathbf{n} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & 3 & 1 \\ 1 & 3 & 2 \end{vmatrix} = 3(\hat{\mathbf{i}} - \hat{\mathbf{j}} + \hat{\mathbf{k}})$$

As **n** is parallel to the plane (i), therefore  $\mathbf{n} \cdot \mathbf{V} = 0$ 

$$(\lambda + 1) - (\lambda - 1) + (2\lambda - 1) = 0$$

$$2 + 2\lambda - 1 = 0 \implies \lambda = \frac{-1}{2}$$

Hence, the required plane is  $\frac{x}{2} - \frac{3y}{2} - 2z - 2 = 0$ 

$$x - 3y - 4z - 4 = 0$$

Hence

$$|A + B + C - 4| = 7$$

$$\left(-\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, \sqrt{\frac{2}{3}}\right)$$
and 
$$\left(-\frac{1}{\sqrt{6}}, -\frac{1}{\sqrt{6}}, -\sqrt{\frac{2}{3}}\right)$$

The angle between in both the cases is  $\cos^{-1}\left(\frac{-1}{3}\right)$ .

**209.** Elimination n between the given relations, we get

$$ul^{2} + vm^{2} + w\left(\frac{al + bm}{-c}\right)^{2} = 0$$

$$\Rightarrow (c^{2}u + a^{2}w)\frac{l^{2}}{m^{2}} + 2abw.\frac{l}{m} + (b^{2}w + c^{2}v) = 0 \qquad ...(i)$$

$$\therefore \frac{l_{1}}{m_{1}} \cdot \frac{l_{2}}{m_{2}} = \text{product of roots} = \frac{b^{2}w + c^{2}v}{c^{2}u + a^{2}w}$$
or 
$$\frac{l_{1}l_{2}}{b^{2}w + c^{2}v} = \frac{m_{1}m_{2}}{c^{2}u + a^{2}w} = \frac{n_{1}n_{2}}{a^{2}v + b^{2}u} \qquad \text{(by symmetry)}$$

If lines are perpendicular, then

$$l_1 l_2 + m_1 m_2 + n_1 n_2 = 0$$
  
$$a^2 (v + w) + b^2 (w + u) + c^2 (u + v) = 0$$

Again, if the lines be parallel, then their d'c are equal so that the roots of Eq. (i) should be equal, i.e. discriminate = 0

**210.** The coordinates of any point on the line  $\frac{x+2}{3} = \frac{y+1}{2} = \frac{z-3}{2} = \lambda \text{ are given by}$ 

$$(3\lambda - 2, 2\lambda - 1, 2\lambda + 3)$$

The distance between the above point and (1, 2, 3) is  $3\sqrt{2}$ .

$$\therefore \sqrt{(3\lambda - 2 - 1)^2 + (2\lambda - 1 - 2)^2 + (2\lambda + 3 - 3)^2} = 3\sqrt{2}$$

$$\Rightarrow \lambda = \frac{30}{17}, 0$$

$$\therefore \text{ Required points are } (-2, -1, 3) \text{ and } \left(\frac{56}{17}, \frac{43}{17}, \frac{111}{17}\right)$$

**211.** The required line is perpendicular to the lines which are parallel to vectors  $\mathbf{b}_1 = 2\hat{\mathbf{i}} - 2\hat{\mathbf{j}} + \hat{\mathbf{k}}$  and  $\mathbf{b}_2 = \hat{\mathbf{i}} + 2\hat{\mathbf{j}} + 2\hat{\mathbf{k}}$ respectively. So, it is parallel to the vector  $\mathbf{b} = \mathbf{b}_1 \times \mathbf{b}_2$ .

Now, 
$$\mathbf{b} = \mathbf{b}_1 \times \mathbf{b}_2 = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 2 & -2 & 1 \\ 1 & 2 & 2 \end{vmatrix} = -6\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 6\hat{\mathbf{k}}$$

Thus, the required line passes through the point (2, -1, 3) and is parallel to the vector  $\mathbf{b} = -6\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 6\hat{\mathbf{k}}$ .

So, its vector equation is

$$\mathbf{r} = (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}) + \lambda(-6\hat{\mathbf{i}} - 3\hat{\mathbf{j}} + 6\hat{\mathbf{k}})$$
or
$$\mathbf{r} = (2\hat{\mathbf{i}} - \hat{\mathbf{j}} + 3\hat{\mathbf{k}}) + \mu(2\hat{\mathbf{i}} + \hat{\mathbf{j}} - 2\hat{\mathbf{k}}),$$
where
$$\mu = -3\lambda.$$

273

So, let the coordinates of A be  $(2\lambda + 3, \lambda + 3, \lambda)$ .

Let the line through O(0, 0, 0) and making an angle  $\frac{\pi}{3}$  with the given line be along OA. Then, its d'r are proportional to

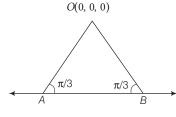

$$2\lambda + 3 - 0, \lambda + 3 - 0, \lambda - 0$$

or 
$$2\lambda + 3, \lambda + 3, \lambda$$

The direction ratios of the given line are proportional to 2, 1, 1. It is given that the angle between the given line and the line along *OA* is  $\frac{\pi}{3}$ .

$$\therefore \qquad \cos \frac{\pi}{3} = \frac{(2\lambda + 3) \times 2 + (\lambda + 3) \times 1 + \lambda \times 1}{\sqrt{(2\lambda + 3)^2 + (\lambda + 3)^2 + \lambda^2} \sqrt{2^2 + 1^2 + 1^2}}$$
$$= \frac{6\lambda + 9}{\sqrt{6\lambda^2 + 18\lambda + 18} \sqrt{6}}$$

$$\lambda = -1, -2.$$

$$\frac{x-3}{2} = \frac{y-3}{1} = \frac{z}{1}$$

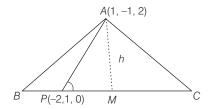

Putting these values of  $\lambda$  in the coordinates of A i.e.  $(2\lambda + 3, \lambda + 3, \lambda)$ , we find the coordinates of A and B i.e. A(1, 2, -1) and B(-1, 1, -2).

So, the equations of *OA* and *OB* are

$$\frac{x-0}{1-0} = \frac{y-0}{2-0} = \frac{z-0}{-1-0}$$

$$\frac{x-0}{-1-0} = \frac{y-0}{1-0} = \frac{z-0}{-2-0}$$
or
$$\frac{x}{1} = \frac{y}{2} = \frac{z}{-1}$$
and
$$\frac{x}{-1} = \frac{y}{1} = \frac{z}{-2}$$

**213.** Clearly, height h of  $\triangle ABC$  is the length of perpendicular from A(1, -1, 2) to the line  $\frac{x+2}{2} = \frac{y-1}{1} = \frac{z-0}{4}$  which passes through P(-2, 1, 0) and is parallel to  $\mathbf{b} = 2\hat{\mathbf{i}} + \hat{\mathbf{j}} + 4\hat{\mathbf{k}}$ .

It is given that the length of *BC* is 5 units.

:. Area of 
$$\triangle ABC = \frac{1}{2}(BC \times h)$$
  
=  $\frac{1}{2} \times 5 \times \sqrt{\frac{71}{7}} = \sqrt{\frac{1775}{28}}$  sq units.

 $=\frac{\sqrt{213}}{\sqrt{21}}=\sqrt{\frac{71}{7}}$ 

**214.** If the coordinates of the point *P* be  $(\alpha, \beta, \gamma)$ .

Then, 
$$\frac{\alpha}{a} + \frac{\beta}{\beta} + \frac{\gamma}{c} = 1 \qquad ...(i)$$

Again d' c of OP are proportional to  $\alpha$ ,  $\beta$ ,  $\gamma$  and hence these are also the d' r of the normal to the plane which is perpendicular to OP and since it passes through P, its equation is

$$\alpha(x - \alpha) + \beta(y - \beta) + \gamma(z - \gamma) = 0$$
  
or 
$$\alpha x + \beta y + \gamma z = \alpha^2 + \beta^2 + \gamma^2 \qquad \dots(ii)$$

It meets the axes in *A*, *B*, *C* and hence the coordinates of these points are  $\left(\frac{\alpha^2 + \beta^2 + \gamma^2}{\alpha}, 0, 0\right)$  etc.

The equation of the plane through *A* and parallel to the *YZ* plane is  $x = \frac{\alpha^2 + \beta^2 + \gamma^2}{\alpha}$ .

Similarly the equations of other planes are

$$y = \frac{\alpha^2 + \beta^2 + \gamma^2}{\beta} \text{ and } z = \frac{\alpha^2 + \beta^2 + \gamma^2}{\gamma}.$$

The locus of their point of intersection is obtained by elimination  $\alpha,\beta,\gamma$  between the three equations of the planes and relation (i)

$$\frac{1}{x^{2}} + \frac{1}{y^{2}} + \frac{1}{z^{2}} = \frac{\alpha^{2} + \beta^{2} + \gamma^{2}}{(\alpha^{2} + \beta^{2} + \gamma^{2})^{2}}$$

$$= \frac{1}{\alpha^{2} + \beta^{2} + \gamma^{2}}$$
Again,
$$\frac{1}{ax} + \frac{1}{by} + \frac{1}{cz} = \frac{\left(\frac{\alpha}{a}\right) + \left(\frac{\beta}{b}\right) + \left(\frac{\gamma}{c}\right)}{\alpha^{2} + \beta^{2} + \gamma^{2}}$$

$$= \frac{1}{\alpha^{2} + \beta^{2} + \gamma^{2}} \qquad [from Eq. (i)]$$

$$\therefore \frac{1}{x^{2}} + \frac{1}{y^{2}} + \frac{1}{z^{2}} = \frac{1}{ax} + \frac{1}{by} + \frac{1}{cz}$$

**215.** Any point on the line is (3r + 2, 4r - 1, 12r + 2).

If it lies on the plane x - y + z = 5, then

$$(3r+2)-(4r-1)+(12r+2)=5$$

$$\Rightarrow r = 0$$

Hence, point of intersection is (2, -1, 2).

Its distance from (-1, -5, -10) is

$$\sqrt{(2+1)^2 + (-1+5)^2 + (2+10)^2}$$

$$= \sqrt{9+16+144} = \sqrt{169} = 13$$

**216.** Any plane through the intersection of given planes is

$$(x + 3y + 6 + \lambda (3x - y - 4z) = 0$$

or 
$$(1 + 3\lambda)x + (3 - \lambda)y - 4\lambda z + 6 = 0$$
 ...(i)

Its perpendicular distance from (0, 0, 0) is 1.

$$\therefore \quad \left| \frac{6}{\sqrt{(1+3\lambda)^2 + (3-\lambda)^2 + (-4\lambda)^2}} \right| = 1$$

$$\Rightarrow \lambda = \pm 1$$

∴ Required planes are 2x + y - 2z + 3 = 0 and x - 2y - 2z - 3 = 0.

**217.** The image of the plane

$$x - 2y + 2z - 3 = 0$$
 ...(i)

in the plane

$$x + y + z - 1 = 0$$
 ...(ii)

passes through the line of intersection of the given planes.

Therefore, the equation of such a plane is

$$(x-2y+2z-3)+t(x+y+z-1)=0$$
  

$$\Rightarrow (1+t)x+(-2+t)y+(2+t)z-3-t=0 \qquad ...(iii)$$

Now, plane (ii) makes the same angle with plane (i) and image plane (iii). Thus,

$$\frac{1-2+2}{3\sqrt{3}} = \pm \frac{1+t-2+t+2+t}{\sqrt{3}\sqrt{(t+1)^2+(t-2)^2+(2+t)^2}}$$

$$\Rightarrow \qquad t = 0, -\frac{2}{3}$$

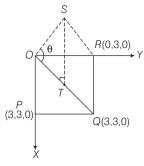

For t = 0, we get plane (i); hence for image plane,  $t = -\frac{2}{3}$ 

The equation of the image plane

$$3(x-2y+2z-3)-2(x+y+z-1)=0$$
  

$$\Rightarrow x-8y+4z-7=0.$$

:. Option (a) is incorrect.

Now, equation of the plane containing the  $\triangle OQS$  is

$$\begin{vmatrix} x & y & z \\ 3 & 3 & 0 \\ 3/2 & 3/2 & 3 \end{vmatrix} = 0$$

$$\Rightarrow \begin{vmatrix} x & y & z \\ 1 & 1 & 0 \\ 1 & 1 & 2 \end{vmatrix} = 0$$

$$\Rightarrow x(2-0) - y(2-0) + z(1-1) = 0$$

$$\Rightarrow 2x - 2y = 0 \text{ or } x - y = 0$$

∴ Option (b) is correct.

Now, length of the perpendicular from P(3, 0, 0) to the plane containing  $\triangle OQS$  is

$$\frac{|3-0|}{\sqrt{1+1}} = \frac{3}{\sqrt{2}}$$

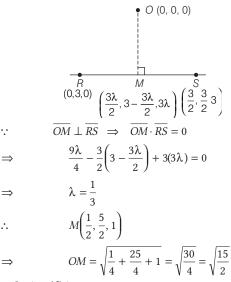

∴ Option (c) is correct.

Here, equation of RS is

$$\frac{x-0}{3/2} = \frac{y-3}{-3/2} = \frac{z-0}{3} = \lambda$$

$$\Rightarrow \qquad x = \frac{3}{2}\lambda, y = -\frac{3}{2}\lambda + 3, z = 3\lambda$$

To find the distance from O(0, 0, 0) to RS. Let M be the foot of perpendicular.

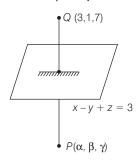

.: Option (d) is correct.

$$\therefore \frac{\alpha - 3}{1} = \frac{\beta - 1}{-1} = \frac{\gamma - 7}{1} = \frac{-2(3 - 1 + 7 - 3)}{1^2 + (-1)^2 + (1)^2}$$

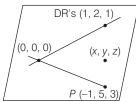

$$\Rightarrow$$
  $\alpha - 3 = 1 - \beta = \gamma - 7 = -4$ 

$$\alpha = -1, \beta = 5, \gamma = 3$$

Hence, the image of Q(3, 1, 7) is P(-1, 5, 3). To find equation of plane passing through

$$P(-1, 5, 3)$$
 and containing  $\frac{x}{1} = \frac{y}{2} = \frac{z}{1}$

which does not satisfy Eq. (iii).

As

So, the DC's of the vector are  $\frac{6}{7}$ ,  $-\frac{3}{7}$ ,  $\frac{2}{7}$ .

**253.** Equation of line passing through (5, 1, a) and (3, b, 1) is

$$\frac{x-3}{5-3} = \frac{y-b}{1-b} = \frac{z-1}{a-1} \qquad \dots (i)$$

$$\left[ \because \frac{x-x_1}{x_2-x_1} = \frac{y-y_1}{y_2-y_1} = \frac{z-z_1}{z_2-z_1} \right]$$

Point  $\left(0, \frac{17}{2}, -\frac{13}{2}\right)$  satisfies Eq. (i), we get

$$-\frac{3}{2} = \frac{\frac{17}{2} - b}{1 - b} = \frac{-\frac{13}{2} - 1}{a - 1}$$

$$\Rightarrow \qquad a - 1 = \frac{\left(-\frac{15}{2}\right)}{\left(-\frac{3}{2}\right)} = 5 \implies a = 6$$

Also, 
$$-3(1-b) = 2\left(\frac{17}{2} - b\right)$$

$$\Rightarrow$$
  $3b-3=17-2b$ 

$$\Rightarrow$$
  $5b = 20 \Rightarrow b = 4$ 

**254.** Given, 
$$\frac{x-1}{k} = \frac{y-2}{2} = \frac{z-3}{3}$$
 ... (i)

and 
$$\frac{x-2}{3} = \frac{y-3}{k} = \frac{z-1}{2}$$
 ... (ii)

Since, lines intersect at a point. Then, shortest distance between them is zero.

$$\begin{vmatrix} k & 2 & 3 \\ 3 & k & 2 \\ 1 & 1 & -2 \end{vmatrix} = 0$$

$$\Rightarrow k(-2k-2) - 2(-6-2) + 3(3-k) = 0$$

$$\Rightarrow -2k^2 - 5k + 25 = 0$$

$$\Rightarrow 2k^2 + 5k - 25 = 0$$

$$\Rightarrow 2k^2 + 10k - 5k - 25 = 0$$

$$\Rightarrow 2k(k+5) - 5(k+5) = 0$$

$$\Rightarrow k = \frac{5}{2}, -5$$

Hence, integer value of k is -5.

**255.** Let the drection cosines of line *L* be *l*, *m* and *n*. Since, the line intersect the given planes, then the normal to the planes are perpendicular to the line *L*.

$$\therefore$$
 2*l* + 3 *m* + *n* = 0 ...(i)

and 
$$l + 3m + 2n = 0$$
 ...(ii)

From Eqs. (i) and (ii), we get

$$\frac{l}{3} = \frac{m}{-3} = \frac{n}{3} = k$$
 [say]

281

We know that,  $l^2 + m^2 + n^2 = 1$ 

$$(3k)^2 + (-3k)^2 + (3k)^2 = 1$$

$$\Rightarrow 27k^2 = 1 \Rightarrow k = \frac{1}{3\sqrt{3}}$$

$$l = \frac{1}{\sqrt{3}} \implies \cos \alpha = \frac{1}{\sqrt{3}}$$

**256.** Since, a line makes an angle of  $\frac{\pi}{4}$  with positive direction of each of *X*-axis and *Y*-axis, therefore

$$\alpha = \frac{\pi}{4}, \beta = \frac{\pi}{4}$$

We know that,  $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$ 

$$\Rightarrow \qquad \cos^2 \frac{\pi}{4} + \cos^2 \frac{\pi}{4} + \cos^2 \gamma = 1$$

$$\Rightarrow \frac{1}{2} + \frac{1}{2} + \cos^2 \gamma = 1$$

$$\cos^2 \gamma = 0 \implies \gamma = 90^\circ$$

**257.** Given, equation of sphere is

$$x^{2} + y^{2} + z^{2} - 6x - 12y - 2z + 20 = 0$$

whose coordinates of centre are (3, 6, 1).

Since, one end of diameter are (2, 3, 5) and the other end of diameter be  $(\alpha, \beta, \gamma)$ ,

then 
$$\frac{\alpha+2}{2} = 3, \frac{\beta+3}{2} = 6, \frac{\gamma+5}{2} = 1$$

$$\Rightarrow$$
  $\alpha = 4, \beta = 9$ 

and 
$$\gamma = -3$$
.

Hence, the coordinates of other point are (4, 9, -3).

**258.** Given equations of lines are

$$x = ay + b, z = cy + d$$

$$x = a'v + b', z = c'v + d'$$

These equations can be rewritten as

$$\frac{x-b}{a} = \frac{y-0}{1} = \frac{z-d}{c}$$

and

$$\frac{x-b'}{a'} = \frac{y-0}{1} = \frac{z-d'}{c'}$$

These lines will perpendicular, if aa' + 1 + cc' = 0

$$l_1 l_2 + m_1 m_2 + n_1 n_2 = 6$$

**259.** We know that, the image (x, y, z) of a point  $(x_1, y_1, z_1)$  in a plane ax + by + cz + d = 0 is given by

$$\frac{x - x_1}{a} = \frac{y - y_1}{b} = \frac{z - z_1}{c}$$
$$= \frac{-2(ax_1 + by_1 + cz_1 + d)}{a^2 + b^2 + c^2}.$$

Thus, the image of point (-1, 3, 4) in a plane x - 2y = 0 is given by

$$\frac{x+1}{1} = \frac{y-3}{-2} = \frac{z-4}{0}$$

$$= \frac{-2 \left[1 \times (-1) + (-2) \times 3 + 0 \times 4\right]}{1 + 4}$$

$$\Rightarrow \frac{x+1}{1} = \frac{y-3}{-2} = \frac{z-4}{0} = \frac{-2(-7)}{5}$$

$$\Rightarrow x = \frac{14}{5} - 1 = \frac{9}{5}, y = -\frac{28}{5} + 3 = -\frac{13}{5}$$
and
$$z = 4$$

Hence, the image of point (-1, 3, 4) is  $\left(\frac{9}{5}, -\frac{13}{5}, 4\right)$ .

**260.** Centre of sphere  $x^2 + y^2 + z^2 + 2ux + 2vy + 2wz + d = 0$  is (-u, -v, -w).

Given equation of first sphere is

$$x^{2} + y^{2} + z^{2} + 6x - 8y - 2z = 13$$
 ...(i)

whose centre is (-3, 4, 1)

and equation of second sphere is

$$x^{2} + y^{2} + z^{2} - 10x + 4y - 2z = 8$$
 ...(ii)

whose centre is (5, -2, 1).

Mid-point of (-3, 4, 1) and (5, -2, 1) is (1, 1, 1).

Since, the plane passes through (1, 1, 1).

$$\therefore 2a - 3a + 4a + 6 = 0$$

$$\Rightarrow 3a = -6 \Rightarrow a = -2$$

**261.** Direction ratios of line normal are

$$(a_1, b_1, c_1) = (1, 2, 2)$$

and direction ratios of a plane are

$$(a_2, b_2, c_2) = (2, -1, \sqrt{\lambda})$$

Since, 
$$\sin \theta = \frac{a_1 a_2 + b_1 b_2 + c_1 c_2}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}}$$

$$= \frac{1 \times 2 + 2(-1) + 2 \times \sqrt{\lambda}}{\sqrt{(1) + (2)^2 + (2)^2 \sqrt{(2)^2 + (1)^2 + (\sqrt{\lambda})^2}}}$$

$$\Rightarrow \frac{1}{3} = \frac{2\sqrt{\lambda}}{3\sqrt{5 + \lambda}} \Rightarrow 5 + \lambda = 4\lambda$$

$$\Rightarrow \lambda = \frac{5}{3}$$

**262.** If  $a_1$ ,  $b_1$ ,  $c_1$  and  $a_2$ ,  $b_2$ ,  $c_2$  are DR's of two lines, then the angle between them is given by

$$\cos\theta = \frac{a_1 a_2 + b_1 b_2 + c_1 c_2}{\sqrt{a_1^2 + b_1^2 + c_1^2} \sqrt{a_2^2 + b_2^2 + c_2^2}}$$

The given equations can be rewritten as

$$\frac{x}{3} = \frac{y}{2} = \frac{z}{-6}$$
 and  $\frac{x}{2} = \frac{y}{-12} = \frac{z}{-3}$ 

:. Angle between the lines is given by

 $\theta = 90^{\circ}$ 

$$\cos \theta = \frac{6 - 24 + 18}{\sqrt{9 + 4 + 36}\sqrt{4 + 144 + 9}}$$
$$= \frac{0}{\sqrt{49}\sqrt{157}} = 0$$

**263.** Since, the centre of sphere

$$x^{2} + y^{2} + z^{2} - x + z - 2 = 0$$
 is  $\left(\frac{1}{2}, 0, -\frac{1}{2}\right)$  and radius of sphere
$$= \sqrt{\frac{1}{4} + \frac{1}{4} + 2} = \frac{\sqrt{10}}{2}$$

Distance of plane from centre of sphere

$$= \left| \frac{\frac{1}{2} + \frac{1}{2} - 4}{\sqrt{1 + 4 + 1}} \right| = \frac{3}{\sqrt{6}}$$

So, radius of circle = 
$$\sqrt{\frac{10}{4} - \frac{9}{6}}$$
  
=  $\sqrt{\frac{30 - 18}{12}} = \sqrt{\frac{12}{12}} = 1$
